IN examining a case of lateral curvature of the spine it is important that the standing height of the legs shall be compared. For this purpose the instrument figured here, which has been made to my design by Messrs. Hawksley and Son, 357, Oxford-street, London, W., is simple in use and accurate in its results. It consists of a thin plate of hard wood, 15 inches long, 2 inches deep in the middle, and tapering to 1 inch at either end, curved to suit the prominence of the abdomen, and having a straight upper edge. It is fitted at the centre of its convex face with a small platform terminating in a convenient handle and bearing a spirit-level. To use the apparatus the patient, with boots off and with the hips exposed, is required to stand erect. A dot is placed over each anterior superior iliac spine with a dermatographic pencil. The instrument is then applied so that the upper edge passes though both dots. If the spirit-level then indicates horizontal the two legs are equal as regards their standing height. If it does not indicate horizontal then slabs of wood of known thickness are placed beneath the foot of the shorter side until the horizontal is gained. The sum of the slabs used gives the difference between the two legs. This method of measurement assumes only one thing—viz., that the pelvis is symmetrical as regards the height of the anterior superior iliac spine above the acetabulum. Any vertical measurement taken from the anterior superior spines themselves with the patient standing on unequal legs requires correction by a very complex and constantly varying formula before it can be accepted as exact, because in the first place, the distance between the anterior superior spines is greater than the distance between the mid points of the heads of the femora (9½ inches to 6½ inches, average measurements), and therefore any difference in the levels of the latter will be exaggerated in the levels of the former; and, in the second place, when the pelvis is tilted sideways the anterior superior spines move up or down, as the case may be, not in straight lines but in curves, owing to the ball-and-socket action of the hip-joint. The usual method of building up the short leg by placing slabs beneath the foot overcomes these objections, and the use of the pelvic level here described does away with the uncertainty of trusting to the eye in judging the restoration of the pelvis to the horizontal.

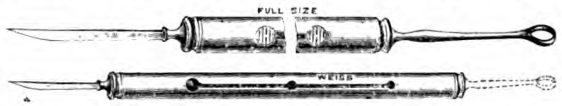
Eastbourne.

## COMBINED TARSAL CYST KNIFE AND CURETTE.

THE removal of tarsal cysts (chalazia) from the eyelids is an operation of some difficulty on account of the smallness of the hold on the eyelids and the slipperiness which ensues when bleeding commences. The difficulty is not lessened by having to change instruments, one to incise and another to scrape out the cyst. To obviate the disadvantages of two independent instruments, I have devised a combination in which both are contained in a metal tube. The knife blade is wedge-shaped, thus enabling the cyst to be opened by one cut, and instead of the usual sharp spoon, which becomes blocked, a sharp ring curette is used. As one instrument is protruded from the tube the other is withdrawn into it, thus tending to prevent injury either to the operator or the patient. The action can be controlled by the fingers of one hand.



Messrs. Weiss of Oxford-street, London, W., have embodied my ideas in a perfectly satisfactory manner, and the instrument can be obtained from them at a moderate cost.

# THE LANCET.

*LONDON: SATURDAY, JANUARY 21, 1911.*

## The Evolution of the Medical Officer of Health.

THE public health service of Great Britain has afforded an example of sanitary administration which has been closely followed by foreign nations and by our own colonies and dependencies, and although there are not wanting critics who are opposed to local government in sanitary matters, and who would have us follow methods more suitable to the conditions of our Indian Empire, the Local Government Board is not likely to be deflected from its ideals of local administration. We may be well resolved to resist the needless encroachments of bureaucracy, and yet perceive that public health conditions cannot always await a settlement by a Parliament entangled in party warfare. The path towards the attainment of sanitary ideals is a long and difficult one, and it is mainly by periodic stimuli put forth by the central body that advances in detailed local administration are made, more particularly in the case of the smaller urban districts and in the rural districts where, as a rule, part-time medical officers are still in power. These part-time officers have in very many instances done excellent work, and a great deal of the sanitary progress which has been effected is in large part due to their efforts which, it may be added, have been altogether out of proportion to the paltry recompense which they have received. But these part-time officers would be, some of them, the first to admit that there are many drawbacks to their employment, and it is clear by an Order recently issued that the Local Government Board considers these drawbacks to outweigh the advantages obtained by leaving the preventive service in the hands of the general practitioner. The future of the general practitioner, which has been of late seriously threatened by so many new social factors, may not at first sight seem to be improved by the new Order, but having regard to the miserable stipends received by so many of the part-time medical officers the pecuniary damage will not perhaps be very great. Moreover, the process of conversion will take very many years to accomplish, so much so that many men of 40 who are now holding part-time appointments may die, still holding them, at a ripe old age. The Order must be taken as little other than an indication of the tendency of central administration. Nor, as we view it, will there be any loss of prestige to the medical profession, but rather the reverse, for at present many who hold these appointments, owing to the insecurity of their tenure and the conditions of their service, do not regard them with much complacency. The loss of emolument to those in general practice will be to a great extent made up in two ways: firstly, those who would be their rivals in general practice by taking the official appointments will leave the field for such practice more open; and secondly, those holding the official appointments, not being their rivals in practice, can be consulted in diagnosis and kept informed on sanitary matters without risk of professional friction.

It must be remembered that the appointment of a whole-time medical officer of health for a very large combined district is not always a success. This fact is evidently appreciated in a Memorandum which has been issued by the Local Government Board in connexion with the new Order. This Order and Memorandum combined contain some very important and far-reaching modifications, the full force of which is only apparent to those who are sufficiently familiar with the subject to enable them to read between the lines. Although the Local Government Board is strongly opposed to the medical officer of health being at the same time a general practitioner, it is clearly in favour, at any rate at present, of the medical officer of health embracing as many appointments of a public nature as will enable him to devote his whole time to public work of one or another description. Indeed, it seems within the realms of possibility that the not far distant future may see a medical officer of health for a relatively small area possessed of a diploma of public health and holding, in addition, one or another, or conceivably all, of the following appointments: school medical officer, superintendent of the isolation hospital, certifying factory surgeon, police surgeon, public vaccinator, district medical officer, and medical officer of the workhouse. Moreover, he may, if qualified to do so, act as consultant in infectious diseases and as the bacteriologist to his own and perhaps other local authorities. It is evidently by some such means as these that relatively small areas will in the future provide themselves with a medical officer of health who shall not engage in private practice, and it will be found by an examination of local appointments how easily a sum of money sufficient to support a whole-time officer may be procured by the fusion of appointments in the sense here contemplated. The coming into operation of such a revolution must be spread over many years, and should not be regarded as spoliation of the general practitioner so much as a rearrangement of duties among medical men whereby there will be more who receive public salaries and less who practise under existing conditions. The particular risk which the medical profession runs at the present moment is that insufficient salaries should be offered and accepted for the discharge of amalgamated duties.

No statement or suggestion is ventured upon in the circular before us as to what the Local Government Board would be likely to regard as a minimum salary, but as the observation is made that the medical officer of health should not be placed in a position of inferiority in the matter of salary to other medical men in the district, it is difficult to see how anything under £500 per annum net as an initial salary could be entertained, the expenses of administration being defrayed. We are glad to see, too, that the Board definitely expresses the opinion that it is "not sufficient merely that a medical man is found who is prepared to accept the salary offered, it is more important that the

salary should be such that it will be worth the while of a capable man to accept it, and to give a sufficient amount of time to his duties." Some important modifications are made by the Order just issued, the provisions of which are already in force as regards the duties of medical officers of health. In the first place, it is definitely laid down that the medical officer of health cannot be expected, as part of his duties, to make a quantitative examination of water, although he may well employ certain qualitative tests for his own guidance. If he is competent to make the former examination the local authority may arrange with him for such purposes. In future, rural as well as urban district councils are to give notice of appointments by advertisement only, although, if the Board sees fit in any special case, it may dispense with this notice. Once appointed for a specified term, this officer, at the expiration of such term, will continue to hold office from year to year, and no further approval by the Board is required unless the terms of the appointment are altered. Moreover, a district council may at any time during the period of limited appointment change such appointment into one without limit of time, all of which provisions mean, of course, that an effort is being made, and that a very praiseworthy one, to bring about greater security of tenure than now obtains. The additions which are made to the duties of the medical officer of health by the new Order are not very onerous except in the event of his annual report not being printed. It is now laid down that this officer shall submit three copies of his annual report to the Local Government Board as well as a copy to his own local authority and to the county council or councils with whom he may be in official relation. Having regard to the very arduous duty of possibly writing out six copies of his annual report, we can well understand the anxiety of the Local Government Board that the local authority should cause the annual report to be printed in order, so that, amongst other things, the district councillors and other persons interested may have an opportunity of perusing it. Another additional duty is the weekly transmission to the Local Government Board, and to the medical officer of health of the county, of a list of cases of infectious diseases notified in his district. He is also required to notify at once to the Local Government Board any case of plague, cholera, or small-pox which may be brought to his notice. The relations of the sanitary inspector to the medical officer of health do not always appear to be quite properly recognised, and consequently the new Order has been modified in such a fashion as to emphasise the fact that the inspector should, as a rule, act under the general supervision of the medical officer of health, who "must be regarded as the head of the public health department of the council."

## The Accounts of Medical Men.

A MEETING of the Hunterian Society is announced to be held at the London Institution, in Finsbury Circus, on Jan. 25th, when a paper on Medical Fees will be read by Dr. F. J. SMITH. The subject, which has often been debated, has once more been brought to the public attention through the issue in the *Times* of Jan. 11th of a letter signed "Senior," in which complaint is made both of the exorbitance of medical charges and of the fact that medical men do not follow the customs of the commercial world by rendering their accounts in detail. "Senior," it will be seen, was making, therefore, a double-barrelled complaint, the first, that of exorbitance, being directed against operating surgeons mainly; and the second, that of deficient business habits, being directed against the general practitioner. "Senior's" letter has led to an interesting correspondence in the course of which there were advanced various reasons in support both of the present standard of fees and of the custom of rendering only a general statement in connexion with charges for professional services, and a leading article in the *Times* of Jan. 17th summed up the situation from the public point of view with great fairness as well as wit.

In all medical affairs there is a public side, and if medical men are prone sometimes to forget this fact, the public is at least equally oblivious of it. But the double interests involved in such a matter as medical charges are too obvious to escape the attention of anyone, and in our opinion it would be a good thing if some of those well-disposed, if critical, laymen who, like "Senior," are unable to understand why there should be any difference between the accounts of a medical man and those of an ordinary commercial firm or of their legal adviser, could attend the debate at the Hunterian Society and explain their difficulties. At such a general discussion the point of view of the public ought to, and would, we feel sure, receive sympathetic attention, and each party to an old quarrel would have details put before them in a new light and in such a way that differences of opinion could be much adjusted. There can be little doubt that if the custom of keeping strict accounts in a business-like manner, rendering them in detail, could be generally adopted by medical practitioners it would prove of great financial advantage to the medical profession, for it would enable the general practitioner to claim many a fee for individual items of special service such as laboratory investigations, letters written, telephone calls answered, and what not, which under the present "lump sum" method are certainly lost to him. Such things are never overlooked in the business-like accounts of the legal adviser, who is held up to us as a model, but we are not certain that the receipt of what an American would call an "itemised" lawyer's bill is greeted with enthusiasm by the public. It is more usual for the public, angrily and unfairly, to call the minor charges extortionate. Most commercial men fail to grasp the crux of the situation, which is that medical aid is in no sense a commodity that is sold but a service that is rendered; a service, the value of which is not fixed or even fixable, but is dependent on many factors—the financial status of the person to whom it is rendered, the professional status of the person by whom it is rendered, the nature of the service itself, and the circumstances and conditions surrounding its rendering. In the business world, and also even in the professional field occupied by the lawyer, the greater part of the work is done in a fixed locality—the shop or office—where a staff of minor assistants is kept, who take cognisance of everything sold or every item of service rendered, duly recording it for the future accounting, while performing all the clerical labour entailed in sending out accounts. These clerks and assistants form part of the business establishment, and the cost of

maintaining them forms part of the consideration on which the scale of charges is based. Without their aid no business man could carry on a business of any magnitude, even if all his work continued to be done in his office. How much more impossible, then, would it be if he personally had to attend to every detail of his work, to call in person upon customers or clients at any hour of the day or night, whenever they wished to make a purchase or to propound a question, and to keep a strict record in a clear businesslike fashion of every detail involved, while no limit was placed to his business hours whereby he could make sure of uninterrupted leisure in which to post up his books.

The question of the magnitude of medical fees is directly linked with the other. The business man, as his business expenses and the cost of apparatus and raw material increase, raises his prices in proportion. Yet the business expenses of the medical practitioner have risen of recent years more rapidly than those of other pursuits. House rent, service, means of locomotion—and, be it remembered, all these items represent more to the medical man than to others of like income, because they are imposed by the needs of his occupation, and not merely conditioned by what is warranted for living purposes from the net profits thereof—professional outfit, all are vastly more expensive than they were a few years ago. The increase of knowledge, moreover, as to the nature of the myriad dangers that surround most forms of medical service, and particularly of surgical intervention, imposes a much heavier burden in labour, time, and money on the conscientious medical man than was the case a very few years ago, in the rendering of the same kind of aid. Why is it that even the gravest operations in surgery are now done with a lesser mortality risk than that which a decade or two back beset even comparatively trivial surgical interference? It is because, as a consequence of the discovery of unsuspected sources of danger, methods of precautionary preparation have been evolved, that entail a greater expenditure of time, trouble, and money prior and subsequent to the actual operation, as well as a much weightier sense of responsibility. Is it nothing to the patient that, as a result of this expenditure, he comes to operation with 20 times less risk of disastrous issue than would have been the case some years ago? And yet, in the face of these facts, the medical man is asked to burden himself with all the clerical paraphernalia and *personnel* of a business office. When patients can consent to do in the case of medical practitioners as business men and lawyers make their clients do—viz., come to an office for everything they want; when they can arrange to be ill and to require assistance only during business hours, thus enabling the medical man to separate entirely his "business" expenses from the cost of his private living, then—and we fear not till then—all medical men may be able to maintain the necessary clerical staff to put their accounts on what "Senior" and those who think like him would consider a business-like footing. The vast majority of medical men will render an account with items when it is required, for they are not without careful methods of recording the details of their services; but to send out such accounts to every patient as a matter of course would entail upon them clerical labour for which the public would have to pay.

# The Influence of Parental Alcoholism on the Offspring.

To minds with a bent for fantastic speculation it might be suggested as a subject of curious consideration why controversy on the question of alcohol is so apt to produce in the controversialists many mental phenomena which have a singular resemblance to the effects which alcohol itself produces on the judgment and the temper of those who take too much of it. May we not, for instance, compare the expansive and genial phase of intoxication with that facile and uncritical mood which makes the participant in debates on this question ready to welcome in support of his side of the argument evidence of a kind that he would never think of offering or entertaining in reference to any other subject under the sun? And may we not again find the analogy of the quarrelsome stage of drunkenness in that pugnacious and aggressive temper, that readiness to discover unintended affronts and to impute discreditable motives, which appears unfortunately to be inseparable from any discussion of even the strictly scientific aspects of this question? These unpleasing characteristics have not been lacking in the acrimonious controversy regarding the influence of parental alcoholism on the offspring, a controversy of which we have heard so much in the last few months, and from which we might perhaps have learned a little more if it had been found possible to conduct the discussion in a less polemical temper.

It will be in the recollection of our readers that the recrudescence of interest in this particular aspect of alcoholism dates from the application to its study by Professor KARL PEARSON and his pupils of the Biometric School of those statistical methods to which they attribute so high a value in bio-social investigations. Their researches on this matter, the result of which was published last May in one of the series of memoirs issued by the Eugenics Laboratory,[1] led them to conclude that the traditional belief which ascribes to parental alcoholism an extremely injurious influence on the offspring is, like so many of the traditional beliefs that have come under the remorseless scrutiny of biometrics, entirely erroneous. So far, indeed, from any such injurious influence being traceable, Professor PEARSON and Miss ELDERTON find that as regards the intelligence, physique, and health of the children dealt with in their inquiry, "the balance turns as often in favour of the alcoholic as of the non-alcoholic parentage." Such a pronouncement not only fluttered the teetotal dovecotes, as it was well calculated to do, it also excited a good deal of surprise and scepticism in quarters quite free from the slightest suspicion of bias; and Professor PEARSON'S data and conclusions were subjected to much hostile criticism both on medical and economic grounds. The criticisms from the medical point of view were formulated more particularly by Sir VICTOR HORSLEY and Dr. C. W. SALEEBY, and they were also urged with much force by several speakers who took part in the debate on this question at the meeting of the Society for the Study of Inebriety on Jan. 10th.

[1] A First Study of the Influence of Parental Alcoholism on the Physique and Ability of the Offspring, by Ethel M. Elderton and Karl Pearson.

Professor PEARSON was not present at this meeting, but had answered his critics with characteristic vigour and reaffirmed his position in a succession of pamphlets issued in the same series in which the original memoir appeared, so that there is no lack of material from which to form an idea of the points at issue between Professor PEARSON and his opponents, and of the grounds of their difference of opinion.

Essentially the discussion has turned on the validity of the data used in the biometric investigation. It appears from the first memoir that these data were derived from two sources —viz., from an account of the children in the special schools for the mentally defective in Manchester prepared by Miss MARY DENDY, and from a report of the Edinburgh Charity Organisation Society dealing with the children attending a large elementary school in that city. From the information furnished in these documents Professor PEARSON worked out the correlation coefficients between the alcoholism of the parents (as estimated by the social workers who surveyed the homes) and various conditions measuring the physical and mental fitness of the children, arriving at the conclusion indicated above. The critics of the memoir object that in these data there is no proof that the "alcoholic parents" suffered from alcoholism at all, at least in the medical sense of the term, which in this connexion means chronic alcoholism, and that there is no evidence *a fortiori* of their having so suffered prior to the birth of the children; and they might emphasise this objection by pointing out that Professor PEARSON'S figures show over 64 per cent. of the Edinburgh schoolboys as having "alcoholic" fathers, and over 34 per cent. as having "alcoholic" mothers, a prevalence of chronic alcoholism which, indeed, the wildest teetotal imagination would hardly have attributed even to Edinburgh! Nor has criticism been confined to the character of the data; the way in which they have been handled has also been called seriously in question by Sir VICTOR HORSLEY and Dr. MARY STURGE in the *British Medical Journal* last week. Professor PEARSON,[2] in a second communication, had taken a like attitude towards the temperance advocates, and it must be admitted that he has little difficulty in showing that a certain amount of what passes for evidence on this question rests on poor foundations. He appears, however, to have taken his "random samples" of evidence as a sufficient proof that all the medical observations indicating the injurious influence of parental intoxications are equally valueless; this is hardly a view that can be accepted without further demonstration, nor is it altogether clear that the method of "random samples" can be applied to the evidence in favour of a theory as a test of the truth of the theory; the value of a conclusive experiment is not affected because a thousand faulty experiments were tried before it and were adduced as evidence in support of the view which it alone, if sufficiently, proves. There are, indeed, very few truths recognised to-day which have not at one time or another been defended by silly arguments and bad evidence as well as by sound arguments and good evidence. However, even among the very few witnesses whom he selects for criticism in his rebutting memoir Professor PEARSON himself recognises that there are differences in scientific authority, and he very rightly treats Professor DEMME'S contribution to the question as deserving a degree of serious consideration that need hardly be given to certain of the more lurid American statistics. Professor DEMME[3] contrasted two groups, each composed of ten families, with whose history he was intimately acquainted. In one group the parents were sober, in the other group one or both parents drank to excess and suffered from chronic alcoholism. And he found that the children of the alcoholic families, as compared with the children of the sober families, showed a very high infant death-rate and a very high incidence of epilepsy, weak-mindedness, and other indications of innate defect. Professor PEARSON argues that the figures given by Professor DEMME are only consistent with the assumption that the cases were selected and were extreme instances, and that they cannot be taken as typical of the normal effects of alcoholic parentage. There remains, of course, the difficulty that even if these be extreme cases they do undoubtedly point to an association between alcoholism in the parent and defect in the offspring; and this difficulty Professor PEARSON endeavours to meet by the hypothesis that in such cases the alcoholism is the expression of a hereditary defect which also accounts for the degenerate conditions in the children. Professor PEARSON, however, implies that he has taken Professor DEMME'S figures from summaries of his work and has not consulted the original paper; had he done so he would have found that Professor DEMME had partially anticipated this objection and had classified his alcoholic families from the point of view of their hereditary antecedents; the families where hereditary taint could, in the opinion of Professor DEMME, be excluded still showed a very high ratio of defect in the children, though not so high as in the families where alcoholism was associated with another degenerative factor in the stock. Apart, however, from its bearing on Professor DEMME'S figures, Professor PEARSON has tried to establish his theory, that extreme alcoholism is an effect of degenerative tendency, by appealing to the experience of the inebriate reformatories; and in an elaborate memoir,[4] written in conjunction with Miss BARRINGTON and Mr. DAVID HERON, he has analysed by the biometric methods a series of 207 observations of female inebriates in the Lancashire Certified Reformatory at Langho. To some extent this seems to be rather a work of supererogation, for, without any statistical proofs, it is common ground that the so called inebriates who have been dealt with under the Inebriates Act of 1898 are practically all cases of congenital mental deficiency, their inebriety, so far as it exists, being merely a secondary and by no means very significant symptom of their innate debility. What Professor PEARSON'S critics would probably dispute is the assumption that such cases are instances of "extreme alcoholism" in the sense in which the term is used in this controversy—that is to say, instances of extreme chronic intoxication; and they would certainly be able to maintain that the natural intolerance of

[2] A Second Study of the Influence of Parental Alcoholism on the Physique and Ability of the Offspring.

[3] Ueber den Einfluss des Alkohols auf den Organismus des Kindes, Stuttgart, 1891.

[4] A Preliminary Study of Extreme Alcoholism in Adults, by Amy Barrington and Karl Pearson, with the assistance of David Heron, D.Sc.

alcohol which these "inebriates" display must of itself prevent any such intense intoxication as might be expected to act on the germinal cells. If we are to ascertain by statistics the relation of "extreme alcoholism" to the mental and physical condition of the drinkers and the drinkers' children, it is not to these cases we should go, but to the instances of well-marked chronic alcoholism which do not find their way to inebriate reformatories at all because they are not generally "inebriates" in the policeman's sense of the word; and the Act of 1898, of course, leaves the diagnosis of the inebriate altogether to the policeman.

It appears very evident, then, that all this outpouring of polemical literature still leaves the question very much where it was. It has not, however, been altogether useless, for it has probably made both parties to the controversy a little less sure of being the sole depositories of truth, and it should also render them a trifle more circumspect with regard to the character and source of the data on which they base their theories. If it has any such effect, it will have brought a very new and acceptable spirit into the discussion of this vitally important bio-social problem.

# Annotations.

"Ne quid nimis"

## ENGLISH URBAN VITAL STATISTICS IN 1910.

THE annual rate of mortality in the 77 largest English towns during the 52 weeks of last year, calculated on the population estimated by the Registrar-General to the middle of the year at 16,940,895, was unprecedentedly low, and did not exceed 13·4 per 1000. In the four preceding years 1906-09 the death-rate in the 76 towns, then dealt with in the Registrar-General's weekly returns, declined successively from 15·9 to 15 4, 14 9, and 14·7 respectively. The Registrar-General's estimate of the population of these large towns, including London, is based on the assumption that the rate of increase that prevailed therein between the last two censuses in 1891 and 1901 has since been maintained. It seems, however, more than probable that on this hypothesis the present population of many of these large towns is over-estimated, and that consequently the aggregate true death-rate is somewhat under-stated. That the death-rate in these 77 towns has shown a steady and persistent decline in recent years, and that it is now unprecedentedly low, seems, however, to be beyond question, and affords conclusive evidence of improved and successful urban sanitary administration. One of the most satisfactory and hopeful features of the recent steady decline in our urban death-rates is the continued decrease of infant mortality. In 1906 the deaths of infants under one year of age in these largest English towns was equal to 145 per 1000 registered births; in the three following years this proportion of infant mortality declined to 127, 129, and 118 respectively; and during the 52 weeks of last year further fell to 115 per 1000. This decline in the rate of mortality in our largest towns has, however, been accompanied by a steady decline in the birth-rate, which was equal to 27·8 per 1000 in 1906, but fell successively to 27·0, 26·9, and 25·7 in the three following years 1907–8–9. The births registered in the 77 towns during the 52 weeks of 1910 were only equal to 24·8 per 1000, showing a decline of 3 per 1000 from the rate that prevailed in 1906. If, however, the aggregate population of these towns is now over-estimated, the calculated birth-rate is somewhat understated, but its marked and steady decline is beyond doubt.

## IODINE AS AN ANTISEPTIC.

As our columns in the past year show, a much simplified method of preparing the skin for operation—painting it with tincture of iodine—has come into vogue and proved very reliable. This method has been in use on the continent for some years, where also the value of iodine as an antiseptic generally seems to be much more appreciated than here. Professor Reclus has called attention to the great value of iodine in the disinfection of the wounds of the hands of workmen, which are difficult to sterilise in consequence of the thick skin covered with grease and dirt. In the *New York Medical Journal* of Dec. 3rd last Major Frank T. Woodbury, of the Medical Corps of the United States Army, claims that iodine is an ideal disinfectant and antiseptic, as it is cheap, easily obtainable, can be carried in small bulk, is efficient in high dilution, and does not damage tissue even when its vitality has been much reduced by traumatism or infection. He has found it invariably successful as a germicide, and though it has great power of penetration he has never seen a case of poisoning, even when the peritoneum was mopped out with it. It can be used to disinfect the area of operation without previous preparation, to sterilise instruments, sutures, dressings, and the hands of the surgeon. However, the continued use of iodine tarnishes instruments and blunts the cutting edge. Major Woodbury uses tincture of iodine entirely to prepare his hands and it rarely causes irritation. It can be removed by means of boiled or raw starch, ammonia, hydrogen peroxide, Fowler's solution, or ether. But after long periods of operation removal of the colour may be very difficult, therefore it is better then to dip the hands in the iodine and immediately decolourise with ammonia. A solution of one teaspoonful of the tincture to a quart of normal saline solution is of a strength of 0·007 per cent. and is most efficacious for the irrigation of catarrhal mucous membranes, as in conjunctivitis and cystitis. According to Major Woodbury, tincture of iodine is the most valuable drug that the railroad and military surgeon can have, while it enables as good results to be obtained in the cottage as in the most modern operating theatre. He suggests that it should be applied throughout to all wounds and raw surfaces infected, or likely to be infected, and abscess cavities. The following are examples which he gives of its use. A soldier, aged 29 years, sustained lateral dislocation of the left knee with severe laceration of the internal lateral and capsular ligaments. The joint was opened and explored with the finger, and the torn ligaments were freshened and sutured with kangaroo tendon, and the skin incision closed with silkworm gut. Tincture of iodine was used for sterilising the surgeon's hands, the area of operation, the depth of the wound, and the sutures. A dry dressing was applied. Convalescence was rapid, and on the eleventh day the patient was going about on crutches. A soldier, aged 24 years, was run over by a heavy wagon and sustained a compound comminuted fracture of both bones of the left leg. He was taken to hospital ten miles across the prairie. Under chloroform Major Woodbury removed the clothing and shoe from the leg and found a nasty wound with 3 inches of tibia lying crossways in the leg, the soft parts much crushed, and numerous splinters of bone. He washed the dust from his hands, dipped them in tincture of iodine, and explored the wound. While the foot was held in extension he refitted the broken fragments of tibia in place, brought the ends of the fibula in apposition, and removed splinters and

shreds of flesh. With long sutures he approximated the severed muscles and thoroughly mopped out the wound with tincture of iodine. Nothing more was done as the tissues were too damaged to stand any manipulation, and wiring the bones would, he considered, have caused extensive necrosis. A posterior wire splint and plaster-of-Paris were applied and a dry dressing, while a large anterior fenestra was cut. The wound was irrigated daily with the iodine salt solution. Some sloughing took place, and when this had ceased repair was rapid. There was never suppuration, fever, or pain. Eight weeks after the accident the wound was healed; the lower end of the fragment had united by firm bony union and the upper by fibrous union.

## SUDDEN ONSET OF ENTERIC FEVER BY HÆMORRHAGIC NEPHRITIS.

ACUTE hæmorrhagic nephritis is a rare complication of enteric fever; still rarer are cases in which the onset of the disease is marked by this complication and the eruption occurs later. An example was reported at the meeting of the Société Médicale des Hôpitaux of Paris on Dec. 2nd, 1910, by M. A. Pissavy and M. Gauchery. On Sept. 7th a youth, aged 18 years, was admitted into the Pitié Hospital with all the symptoms of acute hæmorrhagic nephritis. The urine was of normal quantity, but of a blackish red colour, and contained a large quantity of albumin. Microscopic examination showed granular and blood casts and deformed red blood corpuscles. There were also intense headache, a dicrotic pulse of 100, a temperature of 104° F., bronchitic râles, furred tongue, constipation, enlarged spleen, and œdema of the lower limbs. The history was that eight days previously the symptoms began suddenly after a chill. The dicrotic pulse, the want of correspondence between the pulse and temperature, and the splenic enlargement should have suggested the diagnosis of the renal form of enteric fever, but this possibility was not considered. On Sept. 14th rose spots appeared, diarrhœa replaced the constipation, and Widal's reaction was positive in a dilution of 1 in 50. From the 15th to the 20th the amount of blood in the urine in proportion to the albumin began to diminish. On Oct. 5th the temperature reached normal, the urine was clear, and the quantity of albumin had fallen to half a gramme per litre. On the 9th the patient was discharged, and his urine contained a quarter of a gramme of albumin per litre. M. Pissavy and M. Gauchery have found recorded in the *Thèses de Paris* five similar cases. In the first a man, aged 24 years, after a chill had to take to bed with headache and fever. When taken to hospital a week later he had a temperature of 102·2°, a pulse of 90, a puffy face, and bloody and highly albuminous urine. The appearance 48 hours later of rose spots allowed the diagnosis of acute nephritis to be revised. Recovery ensued. In the second case a man, aged 37 years, was taken to hospital in a state of profound stupor, with a temperature of 102·8°, a pulse of 98, and an enlarged spleen. The urine was scanty and highly albuminous. He had been ill for ten days. On the day after admission the urine was suppressed. Jaborandi was given and produced sufficient diuresis, but the urine was bloody. Five days later rose spots appeared. After three weeks the patient was discharged, the urine containing only a trace of albumin. In the third case a woman, aged 20 years, was suddenly attacked with headache, nausea, giddiness, oliguria, and hæmaturia. The urine contained much albumin. After eight days rose spots appeared and her condition became worse. She died on the fortieth day. At the necropsy the kidneys were found very large and congested. In the fourth case a woman, aged 21 years, was seized with headache, backache, vomiting, and diarrhœa. Five days later she was admitted into hospital in a state of high fever. The urine was scanty and contained a large quantity of albumin. Three days later it became bloody and rose spots appeared. Death occurred on the eighth day of the fever. As in the previous cases, the kidneys were found large and congested. In the fifth case a man, aged 21 years, was admitted into hospital on the fifth day of a severe fever. Forty-eight hours after the onset he noticed that the urine was blackish. On admission the urine contained blood, a large quantity of albumin, and numerous casts. The temperature was 103·5° and the pulse was 101. The liver and spleen were enlarged, and there was gurgling in the right iliac fossa. Death occurred on the thirteenth day of the typhoid fever. These cases show several noteworthy points. The first is the suddenness of onset of the renal symptoms. The second is the prognostic importance of the amount of urine secreted. In two of the three fatal cases there was persistent oliguria; in the other case the quantity of urine secreted is not stated. On the other hand, in the present case the amount of urine secreted was always satisfactory, and in the second case quoted there was only temporary oliguria. But the prognosis of this form of typhoid fever is grave; the six cases show a mortality of 50 per cent. In all the cases the cause of the nephritis seems to have been overlooked until the appearance of the rose spots, although it should have been suspected in consequence of two symptoms—enlargement of the spleen and want of correspondence between the temperature and pulse. The former was about 104° while the latter was only about 90 to 100.

## THE BOROUGH OF PORTSMOUTH AND THE TREATMENT OF PULMONARY TUBERCULOSIS.

WE have received a copy of a special report presented to the council of the borough of Portsmouth on the subject of "The Provision of Sanatorium Treatment and Tuberculin Dispensaries for the Treatment of Inhabitants of the Borough suffering from Consumption," by Dr. A. Mearns Fraser, medical officer of health. The report was prepared in response to a request from the health committee as to the need for the council using its powers under the Public Health Act of 1875 permitting local sanitary authorities to provide sanatorium treatment for patients, whether in receipt of relief or not. The authorities of the borough of Portsmouth are already endeavouring to assist in the combat against tuberculosis by active administration of the Housing of the Working Classes Acts, by giving advice to persons affected with pulmonary tuberculosis, by providing sputum bottles, by disinfecting infected houses, and by affording means for free bacteriological diagnosis. Dr. Fraser in his report gives some details of the approximate cost of building and maintaining a sanatorium, and discusses briefly and in simple language the value of sanatoriums as curative and as educational institutions. He refers to some German statistics and to the published reports of certain English sanatoriums, laying special stress upon the importance of early diagnosis and of effective after-care. He concludes that it is inadvisable at present to provide a sanatorium for the treatment of the patients in the borough of Portsmouth. He is careful to add that he is not in any way opposed to this method of dealing with the disease, but he maintains that any scheme to deal with it comprehensively would be much too costly, and that the expenditure necessary to treat even a small percentage of the cases in the borough by this means would be more successfully applied in another direction. The alternative suggested consists in the establishment of a tuberculin dispensary and giving it one year's trial. It is estimated that the cost will be £600, a sum which is to pay for the dispensary and all expenses connected with it, including medical

attendance, a nurse, a caretaker, drugs, and apparatus. Dr. Fraser makes a few general statements in regard to the nature of tuberculin and its use for diagnosis and treatment. He quotes the published statistics of Dr. W. Camac Wilkinson, and refers to certain other groups of cases treated by tuberculin. He also mentions that he has attended at the Kennington Tuberculin Dispensary, observed the methods there employed, and seen some of the cases. He concludes by recommending the establishment of a tuberculin dispensary, at the same time admitting that this method of treatment must be regarded as on trial, and deprecating any unduly sanguine hopes from it. If the borough authorities decide to carry out these recommendations the results obtained should be of great interest and value, but only if the strictest precautions are taken in regard to the diagnosis of the cases treated by the tuberculin method. We have no wish to criticise the views set forth by Dr. Fraser, which are carefully expressed and are obviously the outcome of an earnest study of the question, but in the light of recent work on the diagnosis of tuberculosis, to which reference was made in the interesting paper by Dr. A. C. Inman published in THE LANCET of Dec. 17th last, the statement made by Dr. Fraser that a rise of temperature after a small dose of tuberculin shows that a patient is tuberculous requires qualification. At any rate, if every case giving such a rise after one small injection is submitted to treatment by tuberculin the results will be of less value than if the cases treated are demonstrated to have active tuberculous lesions.

## PHYSIOLOGICAL VARIATIONS IN THE LEUCOCYTE COUNT.

IT is well known that variations in the normal leucocyte count occur as the result of certain physiological conditions, and the normal limits are usually given as from 6000 to 8000 per cubic millimetre. An interesting paper is published in the *Archiv für Experimentelle Pathologie und Pharmakologie* of Dec. 13th, 1910, by Dr. V. Ellermann and Dr. A. Erlandsen of Copenhagen. They point out that some of these physiological variations are very rapid and evanescent, while others are slower in development and more lasting. They suggest that alterations in the number of leucocytes must in all probability be due to one of three causes—viz., new formation or destruction of leucocytes, alterations in the concentration of the blood, or changing distribution of the corpuscles in the vascular system. Some of the physiological variations can scarcely be due to new formation or destruction, since they occur with too great rapidity. The part played by alterations in the concentration of the blood is difficult to establish. Some observations are on record which tend to show a relation between the blood pressure on the one hand and the number of red corpuscles, the proportion of hæmoglobin, and the specific gravity of the blood on the other. Grawitz showed that paralysis of the vaso-motor nerves could produce a rapid diminution of the concentration of the blood, but it has been pointed out that this is not necessarily due to the alteration in blood pressure. Hot and cold baths cause variations in the number of red and white corpuscles, the white count being much more affected than the red. Some other experiments by Becker and Hess tend to show that variations occur only in the blood in the capillaries, or in that of the veins and capillaries as a result of changes in blood pressure. Tornow, who examined the blood from capillaries after prolonged marches, found on an average an increase amounting to 43 per cent. in the leucocytes, while the increase in the red was only 9 per cent. In the light of these results and of their own experiments, Dr. Ellermann and Dr. Erlandsen conclude that alterations in concentration play at most a subordinate part in the production of physiological variations in the leucocyte count, and they attribute the chief importance to the varying distribution of the leucocytes in the different vascular areas. They then discuss some of the conditions causing more or less rapid variations in the number of leucocytes. The leucocytosis of digestion has been regarded as a true leucocytosis—i.e., as due to the development of fresh corpuscles—but Dr. Ellermann and Dr. Erlandsen see no convincing arguments in favour of this view, and suggest that it may own a similar explanation to the other variations. The leucocytosis of childbirth, which increases markedly after the onset of the pains, diminishes after the birth of the fœtus and increases again during the after-pains, is regarded as due to the associated muscular contraction and as belonging to the group called by Schultz leucocytosis of effort (*arbeitsleucocytose*). Schultz showed that during muscular work the leucocytes might increase from 25 to 50 per cent., a fact confirmed by the observations of Tornow, to which reference has already been made. Hasselbach and Heyerdahl have shown that variations in the leucocyte count occur on sudden change from the erect to the recumbent position and *vice versâ*, a change which they distinguish as a static leucocyte reaction. The explanation offered of these changes is that owing to the increased force of the heart's action and the greater velocity of the blood-stream produced, the leucocytes are forced from their peripheral position in the deeper vessels and hence reach the superficial capillaries in greater numbers. Dr. Ellermann and Dr. Erlandsen have repeated and extended these observations, using special precautions against error, and employing a special method of mixing so as to obviate the defective admixture obtained with the ordinary form of pipette. As a result of 23 observations upon healthy persons and upon convalescents from mild illnesses they obtained in every case a definite alteration in the number of leucocytes on changing from the erect to the recumbent position and *vice versâ*, amounting to 26 per cent., an increase in the first case, a decrease in the second. This reaction is a very rapid one; it attains its maximum in from 15 to 45 seconds after the change of position, and disappears in from 45 to 90 seconds. Some observations upon the leucocytosis of effort showed that this also was of brief duration, lasting only two or three minutes. Psychical influences also appear to modify the leucocyte count, probably through their action upon the heart. Some experiments made upon rabbits showed that the injection of strophanthin led to an increase in the leucocyte count. All these observations are regarded as confirming the explanation already mentioned of these rapid variations in the number of leucocytes.

## THE POLYTECHNIC.

THE Polytechnic, founded by the late Quintin Hogg in 1882, is being rebuilt at a cost of £90,000. This rebuilding fund was inaugurated by a grant of £20,000 from the London County Council and a loan of £20,000 from the City Parochial Foundation. The sum of £50,000 which is needed to complete the fund has been subscribed by Lord Leith of Fyvie, the governors, members, and students of the Polytechnic, and other friends intimately associated with the institution as a memorial to his late Majesty King Edward VII. The money required for the rebuilding of the Polytechnic having been subscribed privately a large number of old members, scholars, students, and travellers are ignorant of the matter. It is believed that the scheme will appeal to all who have ever been identified with the Polytechnic, and that many who are now holding positions of value and responsibility will be glad to have a share in perpetuating the work of the founder and of associating

the new building with the memory of King Edward VII. In consequence of this belief it has been decided to reserve to them the opportunity of contributing the sum of £2500. For this purpose the fund will be kept open until Easter, and subscriptions in amounts varying from £100 to £1 will be received. We are requested to assure all those who have ever been associated with the Polytechnic, wherever they may be, that their help will be cordially appreciated. Subscriptions may be paid in instalments terminating in June, 1912, and should be sent to the Secretary, 309, Regent-street, London, W., or to Mr. J. E. K. Studd, the President and chairman.

## THE LECTURES AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following lectures at the Royal College of Surgeons of England are announced to take place. Mr. Edmund Owen will deliver the Hunterian oration at 4 P.M. on Tuesday, Feb. 14th. Two lectures on "Colour Vision and Colour Blindness" will be given by Dr. F. W. Edridge-Green on Feb. 1st and 3rd; two lectures on "The Immunity Reaction in Relation to Surgical Diagnosis," by Dr. W. d'Este Emery on Feb. 6th and 8th; a lecture on "New Views on the Chemical Composition and Mode of Formation of Renal Calculi and the Metabolism of Calcium in Gout and Allied Conditions," by Professor B. Moore, on Feb. 10th; three lectures on "The History of Mummification," by Professor G. Elliot Smith, on Feb. 13th, 15th, and 17th; six lectures by Professor Arthur Keith, on "The Anthropology of Ancient British Races," illustrated by the Museum Collection, on Feb. 20th, 22nd, 24th, 27th, and March 1st and 3rd; and a lecture by Mr. K. W. Goadby, on "The Association of Diseases of the Mouth with Rheumatoid Arthritis and Certain other Forms of Rheumatism," on March 6th. The lecture hour is 5 P.M. precisely.

## RECENT REPORTS UPON THE INVESTIGATION OF TRYPANOSOMIASIS.

THE difficult problems associated with trypanosomiasis in man and animals continue to receive the careful attention of British investigators. As evidence of this we may mention that at the recent December meeting of the Royal Society no fewer than six papers on this subject were entered on the Proceedings. Two of these papers were contributed by Colonel Sir David Bruce, F.R.S., in association with his colleagues of the Sleeping Sickness Commission of the Royal Society, which has been at work quite lately in Uganda. Both of these contributions deal with "Trypanosome Diseases of Domestic Animals in Uganda," the first relating to Trypanosoma uniforme and the second to Trypanosoma nanum. These two papers are in continuation of a series of former contributions made to the Proceedings of the Royal Society during 1910, and are numbered respectively IV. and V. Trypanosoma uniforme, it appears, resembles T. vivax in shape and general appearance, but differs markedly in size; it also resembles T. vivax in not being pathogenic to the smaller laboratory animals. T. nanum is indistinguishable from T. pecorum either in the living condition or when fixed and stained, but it differs from T. pecorum in not being pathogenic to the smaller laboratory animals. There is no evidence as yet available to show what is the carrier of these two trypanosomes, T. uniforme and T. nanum, but it is probable that the carrier of T. pecorum acts also for T. nanum, since both diseases occur under the same conditions. Four of the papers read in December before the Royal Society were contributed by investigators connected with the Liverpool School of Tropical Medicine, the first of them being entitled "The Life-History of Trypanosoma Gambiense and Trypanosoma Rhodesiense as seen in Rats and Guinea-pigs," by H. B. Fantham, D.Sc. Lond. This interesting paper describes the formation of "latent bodies" from flagellate trypanosomes and the metamorphosis of latent bodies into trypanosomes. The second paper by the same writer, in conjunction with Dr. J. G. Thomson, is a preliminary note on "Enumerative Studies on Trypanosoma Gambiense and Trypanosoma Rhodesiense in Rats, Guinea-pigs, and Rabbits; Periodic Variations Disclosed." These investigations were undertaken at the suggestion of Major Ronald Ross under funds allotted by the Tropical Diseases Research Committee, and under the "Sir Edwin Durning-Lawrence Fund." The third of the papers contributed by the Liverpool investigators is by Major Ronald Ross, F.R.S., and Dr. David Thomson, and comprises further observations on a "Case of Sleeping Sickness Studied by Precise Enumerative Methods." These authorities are of opinion that the periodic increase of trypanosomes observed is due to their active multiplication, and that their decrease is owing to their rapid death and a cessation of multiplication probably depending on certain conditions, including the presence of antibodies in the serum and the large increase of leucocytes, especially mononuclears. The last of the contributions is furnished by Major Ross and Dr. J. G. Thomson, and is a preliminary note on "Experiments on the Treatment of Animals Infected with Trypanosomes, by means of Atoxyl, Vaccines, Cold, X Rays, and Leucocytic Extract; Enumerative Methods Employed." These investigations were conducted by funds given by Sir Edwin Durning-Lawrence for the purpose of testing the effect of cold on disease, and were suggested by Major Ross as a part of the studies made in connexion with a case of sleeping sickness reported upon by him and by Dr. David Thomson. The six papers which we have mentioned above form a valuable contribution to the literature of trypanosomiasis, and demonstrate that British investigators are not being left behind by their continental brethren.

## THE INTERNATIONAL HYGIENE EXHIBITION AT DRESDEN.

IN THE LANCET of Jan. 14th we referred to the forthcoming International Exhibitions and Congresses during 1911, and congratulated the country on the fact that, recognising the importance and value to the nation of representation at such international undertakings, the Government had appointed a permanent department of the Board of Trade to assist intending exhibitors with its experience. We commented especially on the importance of proper British representation at the International Hygiene Exhibition, to be held this summer at Dresden, in view of the mutual advantage that would accrue from a comparative study of German and British attainments in the hygiene of the factory and the workshop and in domestic hygiene. It would seem, however, that there is now some doubt of our representation at this exhibition in consequence of a lack of funds, for an appeal at this late date is being made by an important committee, headed by the Presidents and Ex-Presidents of many of the Royal Colleges, for the sum of £10,000 to meet the necessary expenses. Complaints have reached us that the Government has proved unsympathetic in this particular case. We are aware that the permanent department of the Board of Trade was instituted, not to cut the Gordian knot of difficulties with a cheque in payment of the cost, but to minimise the waste in labour and expense and to obviate the pitfalls due to lack of knowledge in such matters as modes of conveyance, tariffs, custom-house procedure, and local arrangements, the adjustment of all of which it is prepared to undertake. But it will be a serious misfortune if British hygiene fails to be adequately represented at the Dresden Exhibition, because

the Government does not see its way to make the same contribution towards expenses that is being made by all other important Governments. We hope sincerely that the £10,000 for which the scientific committee is appealing in our columns this week will be forthcoming before it is too late.

## THE CHILD-STUDY SOCIETY OF LONDON.

THERE are now 400 members and associate members of this society, and it is desired to increase this number and to make the society more widely known. The honorary secretary, Mr. W. J. Durrie Mulford, 91, Buckingham Palace-road, London, S.W., will be glad to send information as to its objects and activities to all who are interested in child-study. The study of the healthy child in its hygienic, educational, and social aspects is more and more forcing itself upon the attention of the medical man, and prudent parents are now aware of the value of expert guidance, preferably medical, in the upbringing of their children, and of the possibilities of developing the educational and social as well as the moral and physical characters of children along definite and desirable lines. The proper study of preventive medicine in its sociological department includes the study of such problems as form the subjects of the series of lectures and discussions to be held under the ægis of the Child-Study Society during the ensuing months. On Jan. 26th a lecture will be given by Mrs. M Scharlieb, M.D., on the "Recreational Activities of Girls during Adolescence." The lecture on "English Folk Dances," with demonstrations, to be given on Feb. 9th by Mr. C. J. Sharp, promises to prove interesting and attractive; and that on March 9th by Mr. Stewart Macpherson, on "Appreciative Music Study: its Application in the Training of the Child,' will open up a subject to which little attention is usually given in educational schemes. The course of fortnightly lectures will end on April 6th, when Mr. A. R. Ableson will speak on "The Measurement of the Intelligence: with Special Reference to Mentally Defective Children." A conference of combined societies at Halifax in July, under the presidency of Sir James Crichton-Browne, F.R.S., is also announced.

## THE SYNDROME OF SPHENO-PALATINE (MECKEL'S GANGLION NEUROSIS.

Dr. Greenfield Sluder, clinical professor of diseases of the nose and throat in the Washington University, St. Louis, U.S.A., describes in the *American Journal of the Medical Sciences* for December last an interesting symptom-complex, whereby involvement of Meckel's ganglion may be diagnosed with certainty. Meckel's ganglion, as it lies in the pterygo-maxillary fossa, is close to the nasal mucous membrane, and in intimate anatomical relation with the sphenoidal and post-ethmoidal sinuses above, the maxillary sinus in front, and often with the sphenoidal sinus posteriorly. Hence it is not surprising that the ganglion should be affected by inflammation in these cavities. It is in direct association with the superior maxillary division of the fifth cranial nerve, motor fibres leave it on their way to the soft palate and uvula, while some at least of the taste fibres from the tongue course through it. When its function is impaired, then a triad of symptoms may be looked for. First of all, there is wide and characteristic distribution of pain along definite lines, sometimes of great severity. It is usually described as a pain at the root of the nose, in or about the eye, in the upper jaw and teeth, and extending to the ear to take on the form of earache. It is often particularly severe at the mastoid, or at a point about two inches posterior to this, and it may "overflow" to the occiput, neck, shoulder, sometimes even to the arm and hand. There is commonly also pain or itching inside the nose. An objective accompaniment of anæsthesia on the soft palate on the affected side, and over the pharynx as far down as the lower part of the tonsil, is not infrequent. From the motor point of view the configuration of the soft palate is very frequently altered. The palatal arch is usually higher on the affected side, and in movement the uvula and the raphé deviate to the opposite side. During this act the dimple which normally forms in the median line is displaced to the opposite (sound) side. Gustatory changes are interesting and important. It will be remembered that the great superficial petrosal (Vidian) nerve runs backwards from the ganglion to join the facial nerve at the geniculate ganglion, and that along it pass taste fibres coming from the tongue *viâ* the chorda tympani. In almost every case (Professor Sluder has had experience of 60) there has been a diminished and delayed perception of taste in the middle third of the tongue on the same side as the lesion. The neuralgic pains can generally be relieved by the application of cocaine to the nasal mucous membrane covering the spheno-palatine foramen. A single drop of a 20 per cent. solution may be all that is required; or three applications of a saturated solution (67 per cent.) allowed to soak in over the foramen for 10 minutes at a time may effect a lasting cure. Professor Sluder has had excellent results by injecting alcohol into the ganglion. Sometimes the relief experienced when the ganglion is efficiently cocainised is almost startling. A brief statement is made at the close of the article as to the ocular pain in ten cases of glaucoma having been controlled by the application of cocaine to the spheno-palatine foramen.

## HOSPITAL ISOLATION AND TREATMENT OF MEASLES AND WHOOPING-COUGH.

THE result of the important experiment in the isolation and treatment of cases of measles and of whooping-cough in the Metropolitan Asylums Hospitals will be watched with much interest by all who are engaged or interested in public health administration. During the 52 weeks of last year no fewer than 1931 deaths from measles and 1363 from whooping-cough were registered in London, these numbers not differing materially from the average numbers in the ten preceding years. The average proportion of the deaths from these two diseases occurring among children under five years of age is fully 95 per cent.; the fatality of these diseases has therefore an obviously important bearing on the rate of child mortality. On Jan. 7th the Metropolitan Asylums Hospitals and the London Fever Hospital contained 153 cases of measles and 82 of whooping-cough. In connexion with this experiment the experience of the London Fever Hospital, which has for some time been receiving cases of measles, is distinctly interesting. The London Fever Hospital contained two cases of measles at the beginning of last year; during the 52 weeks of the year 207 additional cases of this disease were admitted, 191 were discharged recovered, and 18 cases remained under treatment in the hospital at the end of the year. The fact that not a single death occurred among the 209 cases of measles under treatment during the year affords the strongest evidence of the beneficial effect of the hospital treatment of this disease. No cases of whooping-cough appear to have been treated in the London Fever Hospital during last year, but 210 cases of scarlet fever, 73 of diphtheria, 8 of enteric fever, and 42 of "other diseases" were admitted, making in all 540 cases. It is interesting to note that only three deaths from diphtheria, two from scarlet fever, and one from "other diseases" occurred during the year in this hospital among the total number of cases under treatment. Among the completed cases of scarlet fever the two deaths were only equal to 0·9 per cent., and of the 74 completed cases of diphtheria the three

deaths were equal to 4·1 per cent. These figures testify to the successful treatment of infectious diseases in the London Fever Hospital.

## VULVO-VAGINITIS IN CHILDREN.

THE condition of vulvo-vaginitis in young girls is often a troublesome and somewhat intractable affection, especially in those cases of gonococcal origin. Even after vigorous local treatment the condition is very liable to recur, especially if rigorous precautions in regard to cleanliness are not carried out. Dr. Th. Perrin, of Lausanne, in a paper published in the *Allgemeine Medicinische Central-Zeitung* of Dec. 29th last, describes a method of treatment which he claims gives a lasting cure within a fortnight or three weeks in ordinary cases and within a month even in inveterate cases. He maintains that the condition is not merely a vulvo-vaginitis, but that it is in all respects comparable to gonorrhœa in the adult female, save that in children an extension to the uterine appendages is rare, while vaginitis, which is less common in adults, is almost invariable. He also states that as in adults the cervical canal and the urethra are usually involved and that the relapses and recrudescences are due to re-infection from these parts. Both for diagnosis and treatment Dr. Perrin uses Nitze's urethroscope with a small tube—viz., 25 or 30 Charrière. He takes specimens of pus from the vulva, the os uteri, the vagina, and the urethra for purposes of microscopical examination. The treatment recommended is the application of a 10 per cent. solution of protargol in glycerine. If the urethra is affected the same solution is applied by means of a tube in which is a probe with a small plug of wool soaked in the solution. The cervical canal and the vagina are treated in similar fashion. A compress of 1 per cent. protargol solution is applied to the vulva for a few minutes three or four times daily. Dr. Perrin has treated more than 100 cases by this method with very satisfactory results.

THE King has approved of the appointment of Dr. Theodore Dyke Acland and Dr. StClair Thomson to the consulting staff of the King Edward VII. Sanatorium at Midhurst.

WE deeply regret to announce the death of Mr. Henry Power, late consulting ophthalmic surgeon to St. Bartholomew's Hospital, who was for over 40 years an active member of the staff of THE LANCET.

WE much regret to announce the death within a few weeks of his eighty-ninth birthday, of Sir Francis Galton, the famous anthropologist.

# THE LONDON COUNTY COUNCIL AND THE MEDICAL TREATMENT OF SCHOOL CHILDREN.

WITHIN the next few weeks the position of the present scheme of providing medical treatment for school children in London through the agency of the hospitals may be expected to become critical, the London County Council having asked the Board of Education to agree to the extension for a whole year of the first agreements made with six of the hospitals. It seems doubtful whether the Board of Education will consent to a course which will have the effect of binding the Council to the present system for another 12 months. As an indication of the line the Board will probably take the following sentences from a letter recently addressed to the Council by the central authority[1] may be quoted:—

> The Board now felt it imperative to adopt a more critical attitude in regard to the Council's proposals. ..... The time was approaching when to would be unable to sanction the adoption of further schemes, even in an experimental basis, unless each particular scheme had been carefully thought out as regards all important details, and ..... *had been devised so as not to hamper or embarrass the local authority in adopting any comprehensive system of treatment which might commend itself to them in the future.*

The words italicised would seem to preclude approval of the Council's proposal to continue the agreements for another year. The matter is of such importance that we append some particulars of the report on the subject presented to the London County Council at the end of the year by the Education Committee and the discussion thereon. The Education Committee stated that when the scheme of medical treatment in London was embarked upon it was said to be of an experimental nature, the arrangements with each hospital were limited to twelve months, and a report was promised at the expiration of that time in which the whole question would be reviewed in the light of the experience gained. The period during which most of the agreements with the hospital authorities had been in operation was much less than a year, and sufficient time had not elapsed for a considered judgment on the merits of the scheme to be formed. A report would be presented later. In the meantime it was necessary to deal at once with the question of the renewals of the agreements with six hospitals which would expire during the Christmas recess. These were: the Belgrave Hospital for Children, Clapham-road, S.W.; the Charing Cross Hospital; Hospital for Diseases of the Throat, Golden-square, W.; the London Hospital; the Metropolitan Ear, Nose, and Throat Hospital; and St. George's Hospital. The committee was not able to give full particulars as to the attendance of the children at these hospitals, but from a sample of cases taken at random it appeared that upwards of 85 per cent. of those who attended continued attendance until they were discharged.

### *Modified Arrangements with Six Hospitals.*

The committee went into detail in regard to the agreements with each of the six hospitals. The Belgrave Hospital promised to provide treatment of 880 eye and 880 ear, nose, and throat cases during the year. During the period the agreement had been in force just over 500 cases had been treated in each department; 670 cases should have attended in each department after making allowance for holidays. The committee thought the governing body should be asked to regard its present number of cases as the minimum and to be prepared to treat further cases up to a maximum of 2640, or twice as many as at present. Charing Cross Hospital undertook to treat 1000 eye, 1000 ear, nose, and throat, and 200 ringworm cases. So far 1104 children had attended, and the full number who should have attended was 1734. Although this hospital was central and easily accessible there were within a reasonable distance other hospitals not included in the Council's scheme, where free treatment was available, and to these many parents had had recourse. In this case the committee recommended a reduction in the number of cases to be referred to the hospital to 500 ear, nose, and throat, 440 eye cases, and 200 ringworm cases. At the Hospital for Diseases of the Throat the Council paid 4*s.* for each case. There was no provision in the agreement as to numbers nor as to the payment of the medical staff. It was provided, however, that the staff should be qualified. Between Jan. 24th and Oct. 31st, 1910, 131 children attended, and it was estimated that from 100 to 200 would attend annually. As parents in this district had a wide choice of hospitals, at some of which free treatment was given, no number should be guaranteed to be sent to this hospital. At the London Hospital (3000 eye cases, 1500 ear, nose, and throat cases, and 250 ringworm cases) from Jan. 17th to Oct. 31st 2150 children attended the ophthalmic department, 1331 children in the ear, nose, and throat department, and 198 children in the skin department—total, 3679. The agreement with the hospital provided for 3654 cases in this period. This hospital was available for an extensive and thickly populated area of very poor people, and there was no difficulty in securing the attendance of large numbers of children. In the aural department there was at present a large waiting list. The committee estimated that in this district 9600 children would require treatment for ear, nose, and throat ailments, 3800 for affections of the eye, and 950 for skin diseases. The governing body of the London Hospital should be asked to arrange for the treatment of a minimum of 3000 ear, nose, and throat cases, 3000 eye cases, and 250 ringworm cases annually, and for the treatment of further ear, nose, and throat cases up to a maximum of 6000. The

[1] THE LANCET, Dec. 17th, 1910, p. 1774.

present agreement should continue until the hospital was prepared to deal with the whole or part of the increase. At the Metropolitan Ear, Nose and Throat Hospital, which agreed to take cases up to a maximum of 500, 222 children had attended so far with the Council's voucher cards. The governing body of the St. George's Hospital (700 ear cases, 1100 eye cases, and 200 ringworm cases) had dealt with 1068 children between Jan. 17th and Oct. 31st, and did not desire to renew the agreement, although to avoid inconvenience to the Council it would continue a few months longer. The King's College Hospital had also intimated that it did not desire to renew its agreement when it expired next month. The committee recommended that the agreements with the six hospitals be renewed for 12 months, except in the case of the St. George's Hospital, in which six months was suggested.

The committee gave the following figures with regard to the results which had been obtained at the six hospitals :—

| Hospital. | No. of children asked to attend up to 31/10/10. | No. of children the hospitals could have treated up to 31/10/10. | No. of children who attended up to 31/10/10. | No. of cases which have been investigated as to result of treatment. | No. of children under col. 5 who attended the hospital until discharged. | Percentage of children who attended until discharged. | Cost per case. |
|---|---|---|---|---|---|---|---|

*Discussion by the Council.*

Mr. MATTHEW remarked that these figures showed a serious leakage between the number of children who needed treatment and those who actually received it. The hospital scheme had broken down because no means existed of compelling the attendance of the children at the hospitals. They would not have an efficient scheme until the Council had control of places to which children could be taken and where they would be treated under the discipline of the school. Mr. Matthew referred to infected ears as an ailment for which only compulsory treatment would be effective. The hospital scheme was not cheap, it was not effective, and it was preventing subscriptions from going to the hospitals. At the same time that it hurt the hospitals it hurt the parents, who, before the scheme was inaugurated, could get their children treated for nothing. Nobody was satisfied with the present scheme; one hospital did not want it, another accepted it under protest, and it was carried out generally as a favour to the Council.

Mr. H. E. A. COTTON expressed the hope that arrangements would be made with medical practitioners in North St. Pancras and Islington similar to those in Hampstead, Norwood, and Wandsworth, as these districts were so far from the general hospitals.

Mr. R. A. BRAY was afraid that the Board of Education would not consent to extend the agreements for 12 months, seeing that the report promised on the results of the first year's working had not been presented. He objected to the present scheme because it abolished free medical treatment in London—the hospitals were now rate-supported institutions and would be regarded as such—and because the Council had no means of knowing what went on in the hospitals, or whether it was getting value for money.

Mr. FRANK SMITH said the Council's medical officer had estimated the cost of treatment in clinics at 3*s.* 4*d.* per head, and if that figure was justified the present scheme was not only less efficient but more expensive.

Mr. BRAY moved an amendment to insert in the agreements with the hospitals the words: "Subject to the condition that nothing in the agreement shall prevent the Council's representative from visiting the premises at which treatment is provided when the treatment is being given." He mentioned that those very words were included in the agreements with associations of private medical practitioners.

Miss ADLER, who seconded, believed the hospitals would welcome such a provision, as it would lead to greater co-operation being established with the school medical service.

The amendment was lost, and the recommendations of the Education Committee were then agreed to.

## MEDICINE AND THE LAW.

*An Action against a Surgeon: Abbott v. Ryall.*

ONE of the most important actions recently brought against a member of the medical profession in respect of his treatment of a patient occupied Mr. Justice Phillimore and a special jury for four days last week in the King's Bench Division, and ended in a verdict for the defendant surgeon. The plaintiffs were Mr. G. N. Abbott and Mrs. E. A. Abbott, his wife, and the defendant Mr. Charles Ryall. In October, 1908, the plaintiff, Mrs. Abbott, consulted her medical attendant, Dr. D. Fairweather, who was of the opinion that she was suffering from an internal tumour. After consultation with the defendant an operation was decided upon and was performed by him on Nov. 5th. The action was brought for damages for alleged negligence on the part of the defendant in its performance, the case for the plaintiff being that the defendant had left in the bowel after the operation a swab which he should not have left there; and secondly, that if he were justified in so leaving it, he had not informed those in attendance on his patient, of its presence or taken steps to ensure its ejection. After the operation Mrs. Abbott was able to go to Monaco at Christmas, returning home in March, and subsequently to that time suffered constantly from distension of the bowel, accompanied by severe pain and occasional vomiting. She was medically treated, and in October, 1909, consulted Mr. J. J. O'Donnell, who, according to his evidence, did not connect her condition with the operation, but coming to the conclusion that there was an obstruction prescribed large doses of olive oil, with the result that the swab was passed. With regard to the defendant's attitude on the finding of the swab being brought to his notice, there were attributed to him words implying denial of the use of the swab, which were eventually explained by him. Mrs. Abbott stated that at an interview with the defendant immediately after the passing of the swab he denied having inserted it, saying, when she asked who was responsible for it, "Oh, that is what we want to find out." It was also part of her case, as has been said, that he omitted to inform those present at the operation that it had been left in the bowel. Evidence on behalf of the plaintiffs was given by Mr. Russell Howard, speaking as an expert as to the use of a swab in such an operation, and as to the possible provision for its removal subsequently by tape attached to it. Mr. R. S. Dickson, Dr. Fairweather's partner, who had been present at the operation as anæsthetist, and Dr. Fairweather, who had acted in the capacity of dresser, described what they saw and denied any knowledge of the swab or the receipt of information from Mr. Ryall as to the leaving of it behind. These three witnesses, among other matters, were cross-examined as to the extreme gravity of the operation and of the conditions discovered by it, which they freely admitted, the last-named stating that the conditions found on opening the abdomen were "awful," that it was the worst operation he ever saw, and that it was a wonder that the patient should have survived it. Mr. O'Donnell gave evidence as to his treatment in October, 1909, and as to the condition of the patient then observed by him, admitting in cross-examination that she suffered much pain for some time after the swab had been got rid of, and that during this subsequent period there had been a recurrence of a "lump," the presence of a similar lump before the removal of the swab having been ascribed in the course of the case to it. Mr. O'Donnell also said, in answer to the defendant's counsel, that having heard the operation described, he was of opinion that

the leaving of the swab in the bowel was proper. The defendant, giving evidence, informed the jury that he advised the operation, and that when he commenced it only anticipated the presence of a fibrous tumour. Describing the operation, he deposed that on opening the abdomen he found more serious conditions than he expected. There were adhesions which rendered it a severe and dangerous operation, and a large tear in the bowel occurred. He took immediate steps to stop possible leakage by putting a swab in the bowel, when he proceeded to operate on the diseased parts. He also deposed that after the operation he told the nurse of the presence of the swab and of the necessity that it should be passed, and, further, that he was informed by her six days later that it had been passed. He was under the impression that Dr. Fairweather was aware of its presence, but he had not spoken of it to him. When he had an interview with Mr. Abbott in which the swab was spoken of he was under the impression that there had been an operation on Mrs. Abbott subsequently to the one which he had performed, whereas, although there had been one, it had preceded his by some years. On learning this from Mrs. Abbott next day, he referred to his notes and found the record of the leaving of the swab in the bowel and of the statement by the nurse that it had been passed. Having thus come to the conclusion that the swab was his he communicated with Mr. O'Donnell at once. On behalf of the defendant, evidence was given by Sir Alfred Fripp, Mr. W. E. Miles, and Mr. J. E. Lane, the last-named expressing the opinion that Mrs. Abbott had made a marvellous recovery after a very serious operation, and that Mr. Ryall, the defendant, had displayed great resource. Nurse Elizabeth Powell corroborated the evidence of Mr. Ryall as to his having informed her of the presence of the swab and as to the statement made by her afterwards in error to him. In summing up, Mr. Justice Phillimore directed the jury as to the law that it was for the surgeon to exercise reasonable skill and care, and that the absence of reasonable skill or care constituted negligence in the eye of the law. The burden of proof was on the plaintiffs, and they were not entitled to a verdict unless they had satisfied the jury that there had been a want of reasonable care or skill. After reviewing the evidence he left to the jury the following questions: 1. Was the defendant guilty of negligence by reason of his leaving the swab in the bowel? 2. Was he guilty of negligence by reason of his not informing sufficiently the persons in charge of Mrs. Abbott of its presence? 3. What damages had the plaintiffs sustained? The jury answered the two first questions in the negative, so that no reply was necessary to the third, and judgment was entered for the defendant with costs, a result upon which he is to be warmly congratulated, as is also the Medical Defence Union, which was responsible for the conduct of his case.

*The Sale of Poisons under the Pharmacy Acts, 1868, 1908.*

At the Lichfield county court recently the Pharmaceutical Society sued Mr. R. F. Jacks, a seedsman, for a penalty under Section 15 of the Pharmacy Act, 1868, for having sold nicotine contained in a compound known as "the XL.-all Vaporising Fumigator," contrary to the provisions of the Pharmacy Act, 1868, as amended by the Poisons and Pharmacy Act, 1908. The purchase upon which the action was founded was made by a witness, James Richardson, employed by the Pharmaceutical Society, who gave evidence that having purchased a bottle of the compound mentioned he found on examining it that there was no label on it with the name and address of the seller. The defendant admittedly had a licence under which he might lawfully sell the compound, under Section 2 of the Act of 1908, which, it will be remembered, provides for licences being granted by local authorities for the sale by nurserymen and others of poisons to be used exclusively in agriculture and horticulture. The essential facts of the case were in dispute, the serious suggestions being made that the defendant had not sold the bottle produced in evidence, as it differed from those kept in stock by him, or that the label had been deliberately removed with a view to legal proceedings being taken. Evidence was given by persons who had bought the compound in question from the defendant and by him that in their case the proper label had been on the bottles, and the defendant also gave evidence that to the best of his belief the bottle produced was not his and that he thought that he had none like it in stock. In addition to this, the point of law was taken that the proceedings should not have been under Section 15 of the Pharmacy Act of 1868, but under the new Act of 1908, under which he defendant held his licence to sell. In the latter case the proceedings would have been before magistrates in a court of summary jurisdiction, and not in a county court for the recovery of a penalty. The county court judge gave judgment for the defendant with costs on the higher scale, granting leave to the Pharmaceutical Society to appeal.

## THE NEWEST GARDEN CITY.

IT does seem as if future generations may live to see the abandonment of what used to be called London. The City of London has been for some time no longer a place of residence. Fashionable squares of a century back have in many other districts been converted into tradesmen's premises, and old mansions have become tenement houses let to working men and poor people generally. The radius of four miles round Charing Cross is becoming too small; for some it is too dear; for others it no longer offers the desired amenities. Above all, new conceptions are gaining a firm hold on the more thoughtful householder. He begins to resent the endless payment of rent to enrich speculative builders. If his presence, the rent he is charged, the local trade he promotes by his purchases, enhance the value of land and houses in his district, he wants a share of the wealth he thus helps to create. Again, his better knowledge of the laws of health makes him long, especially if he has the care of children, to get away from noisy, dusty, crowded streets and close-packed houses. The garden city movement is born out of these awakening perceptions. The householder begins to see that he might get a very much better return for his rent. Of course, it has always been cheaper and more healthy to live away from town and out in the open, but this was until recently scarcely practical for those who were engaged in business. The garden city has only become a possibility since the recent and very vast improvements in local traffic. Taking London as an example, what with the "tubes" and the electrification of the District Railway people may live 12 and 15 miles away and yet reach their business office more quickly than when they were only at a distance of three or four miles, but had to travel by horse omnibus. Still, the full advantages of the new situation can only be obtained by coöperation. The solitary individual, with no other resources than his yearly earnings, remains helpless unless he acts in association with others. This bringing into association of intending householders for economic and sanitary purposes is the object of the garden cities.

The last, and also one of the best examples of this movement is the Ruislip Manor Garden City. This endeavour will, we hope, progress harmoniously, though for a beginning most persons concerned quarrel vigorously as to how the name should be pronounced. It appears that in spite of the reservoir and the small river Pinn on the estate the name has nothing to do with the French word for little stream of flowing water, *ruisseau qui ruisselle*, but is pronounced as if spelt Ryslip. This estate belongs to King's College, Cambridge. It is 15 miles from Charing Cross and can be reached in from 18 to 33 minutes from five London stations. It comprises 1300 acres, but the enterprise, known as Ruislip Manor, Limited, is not to be handicapped by having to purchase the whole of this land. The capital of the company now forming will be free for remunerative work, instead of being locked up, as is sometimes the case, by the purchase of land for which there is no immediate use. Therefore there will be money in hand to build drains, make roads, provide lighting, water, &c. It is only when one portion of the estate is thus satisfactorily occupied that another strip of land will be purchased. For 21 years the land will be reserved for the company to purchase. When the estate is fully developed it will hold a population of 30,000. There are to be 3556 houses not exceeding a rental of £30; 3541 under £60; 524 under £100; and 21 houses exceeding £100 annual rental. The area devoted to building plots will be 837 acres, to open spaces 255 acres, and to roads 184 acres. Every tenant will have a garden of his own. There will be public playgrounds and woods, while by careful planning every effort will be made to render the place picturesque. All this is rendered possible by the public-spirited action of the Provost and Fellows of King's College, Cambridge, for they

have consented to sell their estate on terms that involve the purchasers in the smallest possible financial responsibility. Then the Ruislip-Northwood urban and district council has promptly sought to apply the Housing and Town Planning Act of 1909 to this estate, so that it shall be in every respect a model garden city. On its side the company shows its public spirit by renouncing all claims to dividends above 5 per cent. Also the ultimate surplus assets, after repaying subscribed capital and a 10 per cent. bonus thereon, is to be devoted to the benefit of residents on the estate, by such action as the erection of public buildings. Finally, residents will have facilities afforded, if they desire, to purchase the freehold of the land on which their houses are built. Thus the tenants by contributing to create wealth will have the satisfaction of sharing in the benefits that thus accrue. After the capital which renders the venture possible has earned an interest of 5 per cent., all further benefits will be spent as committees representing the residents may deem most agreeable to the inhabitants. So the latter are likely to obtain a large share in the prosperity they create.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

### MEETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on Jan. 12th, Mr. BUTLIN, the President, being in the chair.

The PRESIDENT reported the death, on Dec. 12th, 1910, of Professor Franz König of Berlin, an honorary Fellow of the College, and he stated that he had written to express the sympathy and condolence of the Council with the members of the family.

The Council congratulated Sir Frederick Eve on being knighted.

The Council elected Mr. H. J. Waring a member of the Court of Examiners.

It was resolved to purchase an epidiascope with a complete outfit from Carl Zeiss, Limited.

A report was received from the Museum Committee on proposals for re-arranging the pathological collection and for providing additional accommodation for the display of specimens, including the new medico-legal collection. The report was referred to a joint meeting of the Museum and the Finance Committees.

Mr. Edmund Owen was nominated as a representative of the College to serve on the Council of Queen Victoria's Jubilee Institute for Nurses for three years from March 1st, 1911.

A letter was read from the University of St. Andrews inviting the Council to send a delegate to take part in the celebration of the 500th anniversary of the foundation of the University, which is to take place from Dec. 12th to 15th next. The President was appointed the delegate.

A letter was read from the medical secretary of the British Medical Association forwarding a copy of the following resolution adopted by the Council of the Association with a request that it might receive the consideration of the Council of the College:—

> That it is desirable that diagnosis and treatment of diseases of the eye, including the estimation of refractive errors and retinoscopy, should be compulsory subjects in every medical curriculum, and that every student should undergo a practical examination therein.

The letter was referred to the Committee of Management.

RAG FLOCK.—At a deputation received by Mr. Burns, President of the Local Government Board, on Jan. 13th, the importance of sterilising the raw materials used in the making of rag flock was urged upon his notice by several manufacturers. Mr. Burns expressed the opinion that no amount of sterilisation could render innocuous certain materials which he had himself seen. His view was that washing would probably remove nine-tenths of the objectionable elements. He advised the sections of the trade who on the one hand favoured washing and on the other sterilisation to come to some agreement in the matter and work out for themselves a practical method and standard.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8394 births and 5101 deaths were registered during the week ending Jan. 14th. The annual rate of mortality in these towns, which had been equal to 14·1 and 14·3 per 1000 in the two preceding weeks, further rose to 15·5 in the week under notice. During the 13 weeks of last quarter the death-rates in these towns averaged 14·7 per 1000, against 14·8 and 14·3 in the corresponding quarters of 1908 and 1909. In London the annual death-rate last quarter was equal to 15·3 per 1000, against 13·7 and 13·5 in the two preceding corresponding quarters. The annual death-rates in the 77 towns during last week ranged from 3·6 in Hornsey, 5·9 in King's Norton, 7·6 in Leicester, and 8·4 in Aston Manor, to 21·8 in Bootle, 23·3 in Merthyr Tydfil, 24·2 in Grimsby, and 26·2 in Rotherham. The 5101 deaths from all causes in the 77 towns last week showed a further increase of 389 on the numbers in the two preceding weeks, and included 448 which were referred to the principal epidemic diseases, against 442, 391, and 392 in the three preceding weeks; of these 448 deaths from epidemic diseases, 191 resulted from measles, 87 from whooping-cough, 56 (of infants under two years of age) from diarrhœa and enteritis, 63 from diphtheria, 31 from scarlet fever, and 20 from enteric fever, but not one from small-pox. The fatal cases of measles, which had been 208, 185, and 160 in the three preceding weeks, rose again last week to 191, and caused the highest annual rates, 1·7 in West Ham, 1·8 in Tynemouth, 3·1 in Rotherham, and 3·2 in Sheffield. The 87 deaths from whooping-cough showed an increase of 34 upon the number in the previous week, and were proportionally most numerous in York and Rotherham. The deaths referred to diphtheria, which had been 55 and 76 in the two preceding weeks, declined again to 63 last week; they included 23 in London and its suburban districts, and 3 both in Bristol and in Leeds. The 56 deaths of infants under two years from diarrhœa and enteritis were within one of the number in the previous week; 16 occurred in London, 10 in Manchester and Salford, 7 in Liverpool and Bootle, and 4 in Rhondda. The fatal cases of scarlet fever, which had been 21 and 22 in the two previous weeks, rose to 31 last week, of which 8 were returned in London and its suburban districts, 6 in Liverpool, 3 in Manchester and Salford, and 3 in Bolton. The 20 deaths referred to enteric fever showed a further decline from the numbers in the two previous weeks, and included 5 in London, and 2 each in Derby, Wigan, Sheffield, and Rhondda. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily declined in the nine preceding weeks from 1882 to 1491, had further fallen to 1410 on Saturday last; 135 new cases of this disease were admitted to these hospitals during the week, against 140 and 154 in the two previous weeks. These hospitals also contained on Saturday last 838 cases of diphtheria, 205 of measles, 116 of whooping-cough, and 73 of enteric fever. The 1435 deaths from all causes in London last week (an increase of 107 on the number in the previous week) included 292 which were referred to diseases of the respiratory system, against 263 and 289 in the two preceding weeks. In the 77 towns 180 deaths resulted from different forms of violence, corresponding with the number in the previous week; and 433 inquest cases were registered. The causes of 56, or 1·1 per cent., of the deaths registered during the week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London and in each of its eight suburban districts, in Bristol, Bradford, Newcastle-on-Tyne, Nottingham, Salford, Cardiff, and in 38 other smaller towns; the 56 uncertified causes of death in the 77 towns last week included 7 in Liverpool, 6 in Birmingham, 6 in St. Helens, 5 in Preston, and 3 each in Sunderland, South Shields, and Gateshead.

### HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 889 births and 611 deaths were registered during the week ending Jan. 14th. The annual rate of mortality in these towns, which had been equal to 14·7 and 14·3 in the two previous weeks, rose to 16·6 in the week under notice. During

the 13 weeks of last quarter the death-rates in these towns averaged 14·8 per 1000, only slightly exceeding the mean rate during the same period in the 77 English towns which was 14·7 per 1000. The annual death-rates during last week in the eight Scotch towns ranged from 13·7 and 14·6 in Paisley and Edinburgh to 20·4 and 27·7 in Greenock and Perth. The 611 deaths from all causes in the eight towns last week showed an increase of 85 on the number in the previous week, and included 51 which were referred to the principal epidemic diseases, against 40, 43, and 56 in the three preceding weeks; these 51 deaths were equal to an annual rate of 1·4 per 1000, the highest epidemic rates being 2·7 in Dundee and 4·2 in Perth. Of these 51 deaths from epidemic diseases 18 resulted from whooping-cough, 13 from diarrhœa, 9 from diphtheria, 5 from scarlet fever, and 3 both from enteric fever and measles, but not one from small-pox. The fatal cases of whooping-cough, which had been 7 and 20 in the two previous weeks, declined to 18 last week, of which 9 occurred in Glasgow, 5 in Dundee, and 3 in Leith. The 13 deaths attributed to diarrhœa included 8 of infants under two years of age; 5 deaths from this cause occurred in Glasgow and 3 in Dundee. The 9 deaths referred to diphtheria showed a decline of 5 from the number in the previous week, and included 3 in Glasgow and 2 in Perth. The 5 fatal cases of scarlet fever were within one of the number in the previous week; 2 were returned both in Glasgow and in Edinburgh. Two deaths both from enteric fever and measles also occurred in Glasgow, and 1 each from those diseases in Edinburgh. The deaths in the eight towns referred to diseases of the respiratory system, which had been 92 and 98 in the two preceding weeks, further increased to 130 last week, but were 2 below the number in the corresponding week of last year. The deaths resulting from different forms of violence in the eight towns were 26 last week, against 17 and 19 in the two preceding weeks; and 200, or 33 per cent., occurred in public institutions. The causes of 21, or 3·4 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 largest English towns the proportion of uncertified causes of death last week did not exceed 1·1 per cent.

### HEALTH OF IRISH TOWNS.

In Dublin 230 births and 167 deaths were registered during the week ending Jan. 14th. The annual rate of mortality in the city, which had been equal to 18·9 and 21·5 per 1000 in the two preceding weeks, declined again to 21·4 in the week under notice. During the 13 weeks of last quarter the annual death-rate in the city averaged 19·8 per 1000, whereas in London the death-rate during the same period did not exceed 15·3 per 1000. The 167 deaths from all causes in Dublin last week were within one of the number in the previous week, and included 15 which were referred to the principal epidemic diseases, of which 5 resulted from whooping-cough, 4 (of infants under two years of age) from diarrhœa and enteritis, 3 from measles, 2 from diphtheria, and 1 from enteric fever, but not one either from scarlet fever or small-pox. The fatal cases both of whooping-cough and measles showed a slight decline from those in the previous week. The deaths from all causes included 40 of infants under one year of age, and 38 of persons aged upwards of 65 years; 68, or 41 per cent., of the deaths were recorded in public institutions. The causes of 5, or 3·0 per cent., of the deaths in the city during the week were not certified either by a registered medical practitioner or by a coroner. In Belfast 231 births and 151 deaths were registered during last week. The 151 deaths in this city were equal to an annual rate of 19·8 per 1000, against 12·1 and 16·0 in the two preceding weeks. During the 13 weeks of last quarter the annual death-rate in Belfast was equal to 16·0 per 1000, against 19·8 in Dublin during the same period. The 151 deaths from all causes in this city during last week included but one resulting from any of the principal epidemic diseases—namely, a fatal case of scarlet fever; no fatal case of measles, diphtheria, whooping-cough, enteric fever, diarrhœa, or small-pox was registered. Six deaths resulted from different forms of violence; 12 were registered on the information of the coroner, and 50, or 33 per cent., occurred in public institutions. The causes of all the 151 deaths in the city last week were duly certified either by a registered medical practitioner or by a coroner.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

Fleet-Surgeon George Welch has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in His Majesty's Fleet (dated Dec. 7th, 1910).

The following appointments have been notified:—Fleet-Surgeons: E. F. Mortimer to the *Bellerophon*, on recommissioning; S. H. Birt to the *Carnarvon*; W. G. Axford to the *Good Hope*, on commissioning; and E. Cooper to Queensferry Sick Quarters. Staff-Surgeon: A. X. Lavertine to the *Defence*, on recommissioning. Surgeon: R. J. G. Parnell to the *Victory*, additional, for disposal.

### ROYAL ARMY MEDICAL CORPS.

Colonel M. J. Kerin, C.B., officiating principal medical officer of the Seventh (Meerut) Division, has taken over the duties of Principal Medical Officer of the Bareilly, Garhwal, and Dehra Dun Brigades on the return of Colonel F. B. Maclean from leave. Lieutenant-Colonel J. Maher, from Potchefstroom, has taken over Medical Charge of Queen Alexandra's Military Hospital, Grosvenor-road, London. Lieutenant-Colonel E. J. E. Risk has been transferred from Belfast to the London District. Lieutenant-Colonel W. J. Baker has joined for duty at Cairo. Lieutenant-Colonel M. T. Yarr, medical inspector of recruits in the Scottish Command, has been granted 61 days' leave with permission to travel in France, Switzerland, and Italy. Lieutenant-Colonel R. H. Hall has taken over the duties of Senior Medical Officer at Bermuda. Major S. Macdonald, on arrival from Hong-Kong, has been appointed Recruiting Medical Officer to the London District. Major C. H. Hale, D.S.O., has embarked in the transport s.s. *Rewa* for a tour of duty in India. Major C. R. Elliott, sanitary officer, Third (Lahore) Division, has been transferred from Dalhousie to Lahore. Major L. P. More, staff officer for medical mobilisation stores, Second (Rawalpindi) Division, has been granted two months' combined leave home from India. Major W. Hallaran from the London District, has taken up duty at Lahore. Major F. J. W. Porter, D.S.O., recruiting medical officer, London District, has been transferred to the Southern Command. Major A. E. Smithson from Harrismith has joined for duty at Wynberg. Major A. C. Fox has returned to Tientsin on completion of his leave. Major P. J. Probyn, D.S.O., has arrived home from Hong-Kong. Captain J. B. Clarke has arrived home on duty from West Africa. Captain W. F. Tyndale, C.M.G., has taken over duty at the Royal Infirmary, Dublin. Captain W. C. Croly, Captain F. W. Lambelle, and Captain J. E. Gatt have embarked for a tour of service in India on the transport s.s. *Rewa*. Captain R. G. H. Tate, in charge of the Brigade Laboratory at Ambala, has been appointed a Specialist in the Prevention of Disease. Captain A. D. Jameson, specialist in venereal diseases and dermatology to the Aldershot Command, has been granted one month's leave of absence. Captain C. H. Turner has arrived home, tour-expired, from India. Captain W. F. H. Vaughan, on return to duty from sick leave, has been posted to the Scottish Command. Captain H. J. Crossley has been transferred from York to Richmond (Yorkshire). Captain M. C. Wetherell, from Meerut, has joined the station hospital, Sialkot, for duty. Captain R. P. Lewis, from Bloemfontein, has taken up duty at Wynberg. Captain A. C. Osburn, from Sheerness, has been appointed to Colchester. Lieutenant C. M. Nichol, from Colchester, has taken over medical charge of the troops and their families at Ipswich, in succession to Captain W. Croly. Lieutenant G. O. Chambers has been posted to the Northern Command. Lieutenant J. S. McCombe has been transferred from Bangalore to Malapuram. Lieutenant T. B. Nicholls, from Tidworth, has taken up duty in Egypt. Lieutenant H. G. Robertson, from Richmond, has joined at Sheffield. Lieutenant J. K. Gaunt, Lieutenant E. L. Fyffe, and Lieutenant T. J. Hallinan have been posted to the Irish Command.

### INDIAN MEDICAL SERVICE.

Colonel C. H. Beatson, C.B., Principal Medical Officer, First (Peshawar) Division, has arrived home on leave from India. The services of Lieutenant-Colonel D. St. J. D. Grant, Bengal, have been placed by the Government of India at the disposal of the Commander-in-Chief. Major G. Melville has taken over the appointment of Professor

of Materia Medica at the Medical College, Lahore, relieving Captain A. C. MacGilchrist, whose services have been replaced at the disposal of the Home Department of the Government of India. Major A. Leventon, civil surgeon of Lakhimpur, has been appointed Civil Surgeon at Darrang, Eastern Bengal. Major J. Fisher has taken over duty as Residency Surgeon at Jaipur from Lieutenant-Colonel W. H. B. Robinson. The services of Major W. D. Hayward, civil surgeon of Jaipajuri, Bengal, have been placed permanently at the disposal of the Army Department. Major P. Dee, Madras, has received two months' extension of leave of absence from India on medical certificate. Captain J. C. S. Oxley and Captain R. S. Kennedy have arrived home from India on leave. The services of Captain T. T. Owen have been placed at the disposal of the Government of Burma. Captain C. Dykes, on return from leave, has been appointed Civil Surgeon at Jaunpur. Captain S. H. Lee-Abbott, from Dalhousie, has been posted as Civil Surgeon to Ferozopore. Captain A. K. Lauddie, civil surgeon of Dera Ghazi Khan, has been granted 16½ months' privilege leave combined with furlough. The Lieutenant-Governor of the Punjab has made the following appointments: Captain M. Dalziel, superintendent of the Central Jail, Multan, posted to Multan, on return from combined leave, relieving Captain W. T. Finlayson. Captain W. T. Finlayson, superintendent of the District and Female Jails, Lahore, posted to Lahore, relieving Captain R. A. Chambers. Captain E. D. W. Greig has been appointed to officiate as Director of the Central Research Institute at Kasauli during the absence of Sir David Semple.

### SPECIAL RESERVE OF OFFICERS.

*Royal Army Medical Corps.*

Captain Jonathan Clerke to be Major (dated Jan. 11th, 1911). James Oliver Hamilton to be Lieutenant (on probation) (dated Nov. 9th, 1910).

### TERRITORIAL FORCE.

Colonel Philip E. Hill, administrative medical officer of the Welsh Territorial Division, resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Jan. 18th, 1911).

*Royal Army Medical Corps.*

3rd South Midland Field Ambulance, Royal Army Medical Corps: Charles Ferrier Walters (late Quartermaster and Honorary Lieutenant, 2nd Southern General Hospital) to be Lieutenant (dated Jan. 18th, 1911).

2nd Southern General Hospital, Royal Army Medical Corps: Quartermaster and Honorary Lieutenant Charles F. Walters resigns his commission (dated Jan. 18th, 1911).

*For attachment to Units other than Medical Units.*—James Andrew Simpson to be Lieutenant (dated Oct. 12th, 1910). Captain James King Patrick, from the 2nd Lowland Field Ambulance, Royal Army Medical Corps, to be Captain (dated Nov. 18th, 1910). Christopher Francis Murphy to be Lieutenant (dated Nov. 29th, 1910).

*Attached to Units other than Medical Units.*—Captain (Honorary Captain in the Army) James C. G. Macnab resigns his commission (dated Jan. 18th, 1911).

### THE NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund held on Jan. 10th, Sir J. N. Dick, K.C.B., being in the chair, the sum of £50 was distributed among the several applicants.

### QUEEN ALEXANDRA'S ROYAL NAVAL NURSING SERVICE RESERVE.

The regulations for this service, which have just been issued, state that the Reserve has been formed for the purpose of supplementing the staff of Queen Alexandra's Royal Naval Nursing Service during naval warfare on a large scale. The Director-General of the Medical Department of the Navy will be responsible for the administration and 250 nurses will be employed. This number may, however, be augmented in case of necessity during hostilities.

### DEATHS IN THE SERVICES.

Fleet-Surgeon James Macdonald Rogers, R.N., of the *Orontes*, recently at Malta. He entered the service as a surgeon in 1884, and became fleet-surgeon in 1900. In that year he was awarded he Sir Gilbert Blane gold navy medal.

Deputy Inspector-General of Hospitals and Fleets Matthew Coates, R.N., at his residence at Dawlish on Jan. 13th. He entered the service as surgeon in 1859, became staff-surgeon in 1871 and fleet-surgeon in 1882, in which year he retired with the rank of deputy inspector-general.

## INTERNATIONAL HYGIENE EXHIBITION AT DRESDEN: AN APPEAL.

*To the Editor of* THE LANCET.

SIR,—In the month of May of this year a great exhibition will be opened in Dresden, at which a complete record of the achievement of hygiene from the earliest times up to the present day will be laid before the eyes of the public. Advance will be stimulated by means of over 200 conferences and congresses, and every nation of importance will take part in the endeavour to improve the conditions of mankind.

Since the Government, acting on the advice of the Board of Trade, has decided not to take an official part in this undertaking, there is a grave danger that Great Britain, the admitted leader in hygiene, may be the only nation of importance which is not represented. To save this country from such a disastrous occurrence the vice-presidents of the British Executive Committee, together with a number of men eminent in the world of science, have issued an appeal letter asking for the sum of £10,000. Within a week of the issue of this appeal upwards of £2000 have been subscribed or guaranteed. Sums of 5*s.* (from a "Lover of Peace and Goodwill") up to £100 (from the Corporation of Glasgow) have been received, and guarantees of from £1 to £300 have been given. A very generous offer has been made by Mr. Joseph Rowntree. His family will give £500 if nine others will come forward with at least an equal amount.

With confidence we turn to your readers to save Great Britain from having to hang her head in shame. The world has a right to expect this country to take a prominent part in this friendly international endeavour. The exhibition in Dresden must not be compared with ordinary industrial and "side-show" exhibitions. It will be a vast museum and school, where every legitimate means will be employed in order that its scientific, humanitarian, and educational purposes may be fulfilled. Time is short. The Administration in Dresden asked for a definite reply by the 15th of this month, but has granted an extension.

Subscriptions, both large and small, will be gratefully acknowledged if addressed to the secretary. Cheques should be made payable to the Right Hon. Lord Ilkeston.

We are, Sir, your obedient servants,

THOMAS BARLOW,
Chairman.
ILKESTON,
Hon. Treasurer.
H. W. ARMIT,
Secretary.

47, Victoria-street, Westminster, S.W.

## A RETROGRADE STEP IN DEATH REGISTRATION.

*To the Editor of* THE LANCET.

SIR,—With something akin to a flourish of trumpets, the Registrars-General for the three divisions of the United Kingdom announce, in the first of their Weekly Returns for 1911, that, among other changes, the International List, or Classification, of Causes of Death has been adopted in their several reports.

At the first glance, and from the medical statistician's point of view, this change seems to be a proper and a useful one. But let us look into the matter a little more closely, and from a sanitary standpoint, and the glamour fades. In the modified list "cerebro-spinal fever" takes its place among "other diseases of the nervous system"; "pneumonia" (which, by the way, is advancing by leaps and bounds into the first rank of "the ministers of death") is grouped with "other diseases of the respiratory system"; "diarrhœa

and enteritis," which demand "more than a human hecatomb" from child life every week in the late summer and early autumn year by year, are bracketed with "other diseases of the digestive system"; while "puerperal fever (septicæmia), &c.," are followed by "other causes incident to childbirth."

Now, it will be observed that every one of these diseases undoubtedly belongs to the class of the acute infections, and the infecting agent in the first two of them, at all events, has long since been identified and isolated. And even in the case of summer diarrhœa the active part played by Shiga's bacillus as a causative agent can hardly be questioned at the present day. Further, is not "puerperal fever" universally acknowledged to be due to sepsis caused by sapræmia or septicæmia—forms of toxæmia which in the International List are grouped with tetanus and tuberculosis? Surely small-pox, measles, and scarlatina might just as well be included with "diseases of the skin and cellular tissue," or influenza, diphtheria, and "croup" (which last term should be expunged from any scientific list of diseases) with "diseases of the respiratory system," or enteric fever with "diseases of the digestive system." "Typhus," again, has disappeared from the International List as printed in the English Weekly Return, but it has very properly been retained among "other epidemic diseases" by the Registrar-General for Ireland.

The point, however, which I wish in particular to make is that the transference of such unquestioned acute infections as cerebro-spinal fever, pneumonia, diarrhœa, and puerperal fever from their rightful position under the heading "epidemic diseases," places a formidable stumbling-block in the path of sanitary reformers and medical officers of health. The hands of the State Medicine clock are being put back a quarter of a century at least—to pre-notification days. For when sanitary authorities are asked to add such and such a disease to the schedule of the Notification and Prevention of Infectious Diseases Acts, they will answer: "Oh! the Registrar-General holds that this disease is one of the respiratory system, that other is an affection of the digestive system."

In Ireland on March 31st, 1910, the provisions of the Infectious Disease Notification Act of 1889 had been adopted in 142 out of 158 rural districts, and in 83 out of 95 urban districts. Throughout Great Britain the Act has long since been in force. Writing as a resident in Ireland, I cannot but regard with concern a modification in the list of causes of death which will probably delay (for it cannot ultimately prevent) the including among notifiable diseases under an Act which is now almost universally adopted in the United Kingdom of such death-dealing, yet preventable, maladies as pneumonic fever and epidemic diarrhœa.

I am, Sir, yours faithfully,

JOHN W. MOORE, M.A., M.D., D.P.H.
(1871) Dub., F.R.C.P. Irel.

Dublin, Jan. 16th, 1911.

## ABBOTT AND WIFE *v.* RYALL.

*To the Editor of* THE LANCET.

SIR,—I have seen a cutting from one of the morning papers misrepresenting the answers given to certain questions put to me in a law court last week. My object in writing to you is to make it clear that in my answers the word "anxiety" was only employed in relation to the giving of "instructions" (for after-treatment and observations of results) to "subordinates."

The case was an important one for our profession, and one of the chief points upon which it turned (*vide* the summing-up) was the matter of the instructions given by the doctors to the nurses, and the deductions made by them from the report of the nurses as to the result of the carrying out of those instructions. I was in the witness box more than half an hour, being examined, cross-examined, re-examined, and then questioned by the judge. The two reports which I have seen were brief epitomes. That in the *Times* is a fair one, and demonstrates that that reporter clearly understood the matter in question to be one of "instructions" given by a surgeon to a nurse—his nurse—the nurse he had taken to the case. The word essential to the proper understanding of the questions and answers with which this note is concerned is "subordinate."

I was asked whether "the surgeon would before leaving the case give *instructions* to his *subordinate*," and I replied "Yes." Then to a further question, of detail as to examining and reporting the result of an enema given with the intention of bringing away the swab from the bowel, I said, "As this case shows that is one of our greatest anxieties." And with this statement surely everybody who is used to the after-care of abdominal operations will agree.

I ask you to publish this explanation in case any of your readers may have seen only the second, the unfair and misleading, epitome to which I refer at the beginning of this letter; for in attempting to boil down into one the many questions and answers upon a technical point it misses entirely the matter at issue; and, what is far worse, it at the same time insults my profession and myself by substituting for the word "subordinate" the words "patient's medical adviser."

That this substitution was effected by some reporter who is quite incapable of conveying, even if he can grasp, the technical points involved in the evidence is proved by his senseless jumbling of terms in the preceding paragraph.

I am, Sir, yours faithfully,

ALFRED D. FRIPP.

Jan. 17th, 1911.

## A METHOD OF SERUM DIAGNOSIS FOR TUBERCLE.

*To the Editor of* THE LANCET.

SIR,—The object of my letter with regard to Captain V. B. Nesfield's communication on the serum diagnosis of tubercle was to point out that practically all persons—adults especially—have in their blood antibodies to the tubercle bacillus, and that, therefore, any method of diagnosis must be an accurate quantitative one. It is not a question of presence or absence, but of more or less. I believe I have found such a method by the application of a new principle—i.e., the estimation of the time in which complement absorption takes place with an emulsion of bacteria of definite strength under standard conditions. The process is simple and easy in execution, gives exact results, and is available for all cultivable organisms (though I have only used it at present for tubercle and typhoid), and I think it will be found of great clinical value as affording the simplest method for the application of the Bordet-Gengou reaction in diagnosis.

Captain Nesfield's method of gauging the strength of the emulsion by the appearance (i.e., by guess) is entirely inadequate where quantitative work is to be undertaken. For opsonic work it is different, for here a normal control is used in every case; and even here the careful worker will endeavour, by means of an orientating test, to get his emulsion as uniform as possible on each occasion. In a preliminary communication such as I was making I did not think it necessary to go into details, nor do I now; I may remark, however, that my standard emulsion is carefully sterilised, so that no "short, broad bacillus" can make its appearance, and that controls have been made to show that the disappearance of the complement is really due to specific absorption and not to destruction at the incubator temperature, which does not take place for a much longer period.

I have determined the amount of complement in the serum in a considerable number of cases by an accurate method, and have as yet found no connexion between the figures thus obtained, the amount of antibodies (as determined by the absorption time), and the opsonic index. The question as to whether free complement exists in the circulating blood or not has formed, as any of your readers who are interested in the study of immunity will know, one of the important controversies arising out of the subject, and Captain Nesfield will find an outline of the more important facts bearing on the dispute in my book on Immunity and Specific Therapy, where three pages are devoted to this question. I have also mentioned the fact that opsonin is absorbed along with complement in the Bordet-Gengou reaction, which I thought was now well known.

Captain Nesfield makes numerous definite statements which are entirely unjustified in the present state of our knowledge of the subject—for instance, that a patient suffering from tubercle must constantly be losing complement from intravascular deviation. There is no evidence that this ever occurs, and we should not expect it to do so if there is no free complement in the plasma. Again, he says that an excessive dose of tuberculin would probably reduce the complement in the blood and be a source of danger. I am aware that some

observers have found a diminution of the complement in the serum during anaphylactic shock, but this is not generally accepted, and even during a severe tuberculin reaction I have not found the amount reduced. Even if it were, there is no proof that it would be harmful. In my own measurements of the amount of complement in the different conditions I have found no relation whatever between the amount and the severity of the disease or any clinical indication. Lastly, he says that a falling opsonic index would at once show this and indicate danger. I am not prepared to say that there is no connexion between the opsonic index and the amount of complement, but if there is it is quite certain that it may be masked by other factors, and that a high index does not necessarily mean a large amount of complement, or *vice versâ*.

In conclusion, may I point out that all hæmolytic observations on Hecht's method are liable to be vitiated by the fact that the amount of amboceptor is subject to variations, as yet unmeasured, and that this, as well as the variation in the amount of complement (which can be measured easily), renders accurate work impossible, or at least arduous in the extreme?

I am, Sir, yours faithfully.

Jan. 16th, 1911. W. D'ESTE EMERY.

## RECENT VIEWS AS TO THE MECHANISM OF ANTISTAPHYLOCOCCAL DEFENCE.

*To the Editor of* THE LANCET.

SIR,—Amid so much that was interesting in Dr. F. W. Andrewes's Croonian lectures[1] it was disappointing to find how little attention the lecturer gave to the medical aspect of his subject. He told us that the new facts prove the immense importance of phagocytosis in pyogenic, and its lesser importance in non-pyogenic, infections; but, apart from this, I hardly remember a single practical application he has made of his discoveries. He has certainly not applied them to the solution of any of the more thorny problems which vex the practitioner in his daily association with infectious ailments. Perhaps, considering the nature of Dr. Andrewes's work, it could not well have been otherwise. In artificial infections local inflammations are much less prominent than they are in natural illness. To the intravenous inoculator of rabbits an infection comes to be little more than a useful starting point for a circulatory leucocytosis, whose source and fluctuations are to be examined in detail, but whose destination in the actual conflict with the bacteria may be left in a convenient vagueness. To the clinician, however, the sole interest of such researches lies in the light which they shed upon disease; nor, allowing for the extreme looseness of the parallel, is there any reason why the phenomena of animal infection should not be utilised for the purpose of illustrating human pathology. Looking at the experiments in this rather utilitarian way, I wish to consider how views which I outlined in a letter to THE LANCET of June 25th last are affected by Dr. Andrewes's and other recent work.

Let me recall that to Dr. Andrewes, as to most present-day authors, the main defence in staphylococcal infections is phagocytosis, while my letter was designed to show that in the furuncular group the chief danger, that from the spread of the local inflammation, is probably combated by antitoxis. In the first place, were leucocytes the chief defence in carbuncle we should expect a gradual arrest of the complaint, as they gradually got the upper hand of the bacteria. The fact that expansion goes on with no apparent diminution of rapidity suggests rather a new force brought suddenly to bear than the final effort of an agent that had been slowly wearing down the bacterial attack. Moreover, the time at which arrest takes place, some days at least from the onset, agrees well with the time required for the preparation of an antitoxic, and not so well with that required for the institution of a phagocytic, defence. Not only as regards defensive preparation, but still more from the point of view of the relative strength of the opposed forces, the time of arrest is unfavourable to the phagocytic theory. As there must be during the expansion of a carbuncle the same constantly increasing proportion of bacteria and toxins to defending leucocytes as I have pointed out there is to defending tissues, arrest ought upon that theory to take place at the very beginning of the trouble, when defence is relatively strong in comparison with the attack, and not, as it actually does, at a stage when things are most favourable to the invading bacteria. Further, the likelihood of the leucocytes contributing materially to arrest will be the smaller the larger, we suppose, the number of them to be that are present in the first stage of carbuncle. A small leucocytosis might be thought insufficient to kill the bacteria. A large one would indicate the breakdown of the phagocytic defence in circumstances that were well suited to its effective exercise. On the evidence hitherto available one had imagined the number to be comparatively small. The relatively mild symptoms, the contrast, so much more marked than the common descriptions imply, between the characters of the swelling in the earlier and in the later stage, the kind of juice which can be squeezed from the section, all pointed to the probability of a rather small leucocytosis. Dr. Andrewes's experiments, however, suggesting a large early circulatory leucocytosis, make it almost certain that the part taken by leucocytes in the constitution of the early swelling of carbuncle is a large one, and so far are unfavourable to the phagocytic theory. Significant, too, in the present connexion is the recent surgical reaction against the theory, due partly to the disappointing results of the vaccination treatment, partly to a growing conviction as to the enormous anti-bacterial powers of the healthy tissues. The immunising functions of the leucocytes are now admitted to have been a good deal exaggerated, and to be still very imperfectly understood. Basing upon clinical experience, as the only safeguard against the like errors in future, we have to look for a theory which shall at once meet the difficulties I have enumerated, and escape a still more fatal objection to the current phagocytic doctrine to which I will come presently.

Obvious as are the above considerations, the force of some of them would clearly be lessened, were it permissible to regard the nascent leucocyte as having a higher defensive value than the ordinary circulatory one. The leucocytes formed in connexion with the bone-marrow changes, which occur some days after infection, might then be credited with an arrestive power which the first arrivals at the inflamed focus were without. While it is possible that in carbuncle such a higher arrestive power is actually exerted by the later-formed leucocytes, observation of the course of the complaint makes it extremely unlikely that the mode of arrest is phagocytic. Though no one has hitherto paid any attention to the facts tending to show the existence and successive neutralisation in carbuncle of at least two toxins, both the facts themselves and their bearing on the doctrine of immunity are sufficiently plain. The ultimate reason, which bars the phagocytic theory, is the circumstance that, under normal conditions—i.e., in carbuncle occurring in otherwise fairly healthy persons without complications—constitutional symptoms are met with chiefly in the period extending from arrest of the complaint onwards. The notion that we have to do with only one toxin will therefore imply that it can exert a disorganising effect on the tissues, when present in quantity, which produces little or no constitutional disturbance, and be without power to cause local damage, when in quantity capable of causing general symptoms of a quite noticeable order. Allowing then that an idea which involves an absurdity must itself be absurd, we seem driven to the alternative of admitting the toxic duality. But if in carbuncle two poisons are successively got rid of, clearly the neutralisation of the first cannot have been due to phagocytosis, for in that case the second must have ceased to be produced. In a word, the continued operation of the constitutional poison long after the tissue-destroyer has ceased to give trouble is a fairly obvious indication that the latter has been neutralised by an antitoxin.

Those who have had practical experience of infectious ailments will usually have no difficulty in admitting, as the preceding argument requires us to admit, that the constitutional symptoms of carbuncle are really toxic in character. In medicine, however, there are many different view points, and we read in the Croonian lectures without any surprise that the "chief clinical symptoms of infective disease depend on the work of defence." Dr. Andrewes nowhere says upon what particular defensive work they depend, but the plain inference is that it is the leucocytosis. There is nothing else in his analysis of the factors of immunity with

[1] Croonian Lectures on the Behaviour of the Leucocytes in Infection and Immunity delivered before the Royal College of Physicians of London by Dr. F. W. Andrewes, THE LANCET, June 25th (p. 1737), July 2nd (p. 8), 9th (p. 83), and 16th (p. 153), 1910.

which it is possible to connect them. First, then, as regards a possible relation of the symptoms to a circulatory leucocytosis, it is perhaps sufficient to say that there is a good deal of evidence against, and none at all in favour of, the idea. The facts bearing on the subject are detailed in the lectures, and it would be idle to repeat them here. They make it probable that in a good many infections the symptoms are due to a circulatory leucopenia and wholly impossible to treat seriously the suggestion that in carbuncle they may result from the opposite condition. There remains the question of their possible connexion with the local leucocytosis. No one, of course, doubts that the local symptoms of inflammatory complaints are due largely to local tension. The point is whether the general ones are similarly determined. Can we regard the fever, chills, sickness, faintness, malaise, and so forth, as resulting from the local accumulation of leucocytes? We have it on the best authority that tension alone will cause rise of temperature, but we are dealing in carbuncle with a very different condition from that of an aseptic wound with confined discharges. We have, on the one hand, the symptoms I have just mentioned, and, on the other, a sore teeming with bacteria and their toxins. Is it more reasonable to suppose that these are related as effects and cause, or that they have no relation to one another at all, and that the source of the symptoms is a tension caused by leucocytes which have been brought to the part for no other reason except as a defence against the bacteria? The inquiry seems to admit of only one answer, unless we are to form a very different idea of nature's therapeutic methods from any that has been hitherto entertained. It may be added that in carbuncle the greatest intensity of the symptoms does not correspond very accurately with the maximum tension. The symptoms are often most marked after the tension has been somewhat relieved—a fact which in another respect favours the intoxication notion. When the extreme pressure on the absorbents and capillaries is relieved the poisons will be more freely taken up.

Closely connected with Dr. Andrewes's symptomatology is his statement that the pyococci do not form soluble toxins. In my June letter I assume that the poison of carbuncle is not very readily absorbed, but have never thought of it as either a solid or as remaining inside the bacteria, in the manner apparently imagined by Dr. Andrewes. On the latter view we should have to assume the intra-bacterial neutralisation of a toxin, which had exerted extremely powerful extra-bacterial effects, an idea which, though savouring of the "transcendental pseudo-chemistry," which Dr. Andrewes denounces, might perhaps be admitted. But a more serious difficulty presents itself as to how the bacteria are to get through the immense accumulation of leucocytes in order to produce the late constitutional symptoms of carbuncle. It has been alleged that in the great destruction of tissue which often takes place the bacteria may enter the ends of severed blood-vessels; but this, while it certainly occurs at times, seems insufficient as a general explanation. What Dr. Andrewes says as to fluctuations in the later systemic leucocytosis is of interest in relation to the question of the solubility of the toxins. The fluctuations receive no explanation on his theory of chemiotaxic attraction, but if we suppose the stream of leucocytes to be a response to local absorption it may be expected to vary with the latter. The fact that constitutional symptoms may in certain cases be elicited by pinching a carbuncle shows that absorption varies with the local pressure. Therefore, it will vary with the variations of pressure which must occur naturally in the course of carbuncle. It will vary also with other natural variations—variations, e.g., in the activity of the capillaries and lymphatics. Such slight normal variations could scarcely, however, affect materially the absorption of bacteria, but might cause alterations in the rate of absorption of a more or less soluble toxin. Also the somewhat variable, fitful, or wavy character which patients at times ascribe to their sensations fits in very well with the notion of a varying absorption from the focus. Thus many indications concur with Dr. Andrewes's discovery of fluctuations in the late staphylococcal leucocytoses to lend countenance to the notion that the systemic poison of carbuncle may possibly be fluid.

Finally, I may refer to the work of those busy allies of Dr. Andrewes, who approach the subject on its more practical side. To expect a practitioner to prove that his treatment is an essential element in the cure is to impose a test which has never been considered entirely fair. It will always be open to critics, and I am afraid some of them have been unkind enough to avail themselves of the opportunity, to say that cure would have occurred just the same without the special measures employed. Still, the vaccinationist is not quite the kind of person to be browbeaten, and there is nothing very extravagant in the belief that had he succeeded in stopping a carbuncle he would certainly have claimed to be able to do so. Now, I have searched the published writings with some care, and have nowhere seen it asserted that vaccination will cause a carbuncle to stop short of the size it would in the natural unvaccinated course of things have attained. The statements are either quite general or indicate that the treatment is of use, not in the arrest, but in the cure of the complaint. Thus Western records nine cases in THE LANCET of Nov. 23rd, 1907, cured by aureus vaccine, which had all been previously treated in the ordinary way "without showing any adequate attempts at repair." Others speak of the "efficacy of the vaccine in breaking down chronic indurations." It is certain that the vaccinators have not yet been able to point to results comparable with those obtained from the serum treatment in diphtheria. They have not shown us the brawny induration of an enlarging carbuncle changed in the course of a few hours into a healthy granulating sore. Their failure is confessed in the fact that they one and all recommend the use of an auto-vaccine, during the preparation of which the carbuncle will in almost every case have already become arrested. That the injections should promote healing is what many facts of general experience would lead one to expect. Though we do not know in what precise way the staphylococci interfere with repair, the importance of phagocytosis in the late stage of carbuncle is established quite independently of the vaccine therapy. Speaking for myself, it has never occurred to me to think that the systemic poison in carbuncle is destroyed by antitoxis. In my letter I say that "it is scarcely at all neutralised by antitoxins." It is doubtless eliminated from the body by the ordinary channels and destroyed locally as the leucocytes gradually get the mastery of the bacteria. Thus, in carbuncle, while the main danger from tissue destruction is provided against by antitoxis, the lesser from non-healing and systemic intoxication is dealt with by phagocytosis, just as in the contrasted case of diphtheria the greater peril from systemic poisoning is met by antitoxis, while the lesser from the local inflammation is probably counteracted by phagocytosis. Both complaints show us antitoxins forming, as it were, the last line of defence against bacterial attack.

I am, Sir, yours faithfully,

I. B. MUIRHEAD.

Stoke Newington Common, N., Dec. 27th, 1910.

## A MEDICAL CLUB IN PARIS.

*To the Editor of* THE LANCET.

SIR,—Dr. Madeuf, whom I know personally, has asked me to draw attention to the Médical Club Étranger in the English medical papers. I have visited the place, which is thoroughly well built and organised. As it is likely to be of great use to English medical men visiting Paris, I think it worth while to draw their attention to it.

I am, Sir, yours faithfully,

H. J. JOHNSTON-LAVIS.

Beaulieu, Alpes-Maritimes, Jan. 9th, 1911.

## TUBERCULOSIS AND STATE INTERVENTION.

*To the Editor of* THE LANCET.

SIR,—Our attention has been drawn to certain ambiguous references to the Conference on Tuberculosis held recently at Edinburgh. These concern more particularly the resolution which was passed at the close of the discussion on "The Working Man in Relation to Tuberculosis." The suggestion has been made, and is prominently repeated by the authors of "The Conquest of Consumption" in the preface to the second edition, that the Conference "was practically unanimous in the opinion that some form of State intervention was necessary." As occurring in the introduction to

an elaborate plan of campaign, in which the authors relegate in wholesale fashion to the State responsibility for the handling of the tuberculosis problem, the sentence seems to us misleading.

We think it right to say that the resolution which was adopted by the Conference was limited to the question of working men's invalidity insurance. The actual terms of the resolution were as follows:—

That the special attention of the Chancellor of the Exchequer, Government, and Parliament be called to the great importance of giving the prevention and treatment of tuberculosis a prominent place in the proposed scheme of invalid insurance.

We are, Sir, yours faithfully,

W. LESLIE LYALL, M.B. } Joint Honorary
JAMES MILLER, M.D. } Secretaries.

Edinburgh, Jan. 17th, 1911.

## A POINT IN CHOLELITHIASIS.

*To the Editor of* THE LANCET.

SIR,—In your issue of Dec. 24th last Dr. Duncan Macartney asks for instances where large numbers of gall-stones have been removed by operation. In February, 1910, I operated upon a male patient of Dr. W. B. Chapman of Rochdale, and removed 3007 gall-stones, varying in size from a hazel nut to a split pea, and all facetted. The stones are now in my possession, though I have not myself verified their number, the patient having counted them during his convalescence. He had suffered for many years from severe attacks of colic, each of very short duration, and on no occasion followed by jaundice. The gall-bladder appeared, apart from the presence of these calculi, to be normal, and I performed merely a cholecystostomy. His convalescence was interrupted by an attack of pulmonary embolism in the third week, followed by embolic pneumonia, from which he ultimately made a good recovery, and he is now in excellent health.

I am, Sir, yours faithfully.

Manchester, Jan. 16th, 1911. ARTHUR H. BURGESS.

THE PRINCE FRANCIS OF TECK MEMORIAL FUND.—At the Memorial Concert for the late Prince Francis of Teck, to be held in aid of the funds of the Middlesex Hospital at Queen's Hall on Jan. 24th, the programme will consist of Beethoven's overture, "Leonora III.," Verdi's famous "Requiem," with 500 voices and instruments, by the Brighton Choir and Festival Orchestra, under Mr. Joseph Sainton, and Wagner's triumphant "Heldegungs-Marsch." The soprano parts will be sung by Miss Alys Bateman, who needs no introduction. Other artists on the programme are Hannah Jones, Ben Davies, and Edmund Burke, the last-named by permission of the Italian Opera Company, Covent Garden.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill announce for publication a new edition of Vol. IV. of "Allen's Commercial Organic Analysis," which has been rewritten under the editorship of Mr. W. A. Davis, B.Sc., and Mr. S. S. Sadtler, S.B. The subjects and authors are as follows: Resins, by M. B. Blackler; India-rubber, Rubber Substitutes, and Gutta-percha, by E. W. Lewis; Hydrocarbons and Ketones of Essential Oils, by T. M. Lowry; Volatile or Essential Oils, by E. J. Parry; Special Characters of Essential Oils and Tables of Essential Oils, by H. Leffmann and C. H. LaWall. It will be seen that each subject is handled by an expert in his department.—Messrs. George Newnes, Limited, announce the impending publication of "Careers for Men, Women, and Children," a book describing most occupations, giving information regarding education or training required, length of time taken in preparation, the cost of qualifying, incomes to be made, and prospects afforded by the employments.—Messrs. W. B. Saunders Company announce that they have in the press for immediate publication a work on "The Anatomic and Histological Processes of Bright's Disease," by Dr. Horst Oertel, director of the Russell Sage Institute of Pathology, New York. In the preparation of this work the author has had in mind a twofold aim—to present the visual picture of nephritis and to prepare the proper way for the understanding of the genesis of the disease.

## THE HOUSING PROBLEM IN SOUTH WALES.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Merthyr Tydfil, Dec. 1st, 1910.

*The Valley of Martyrdom.*

THE problem of the housing of the poor, always difficult and nowhere satisfactorily solved, has been stated to be specially acute in both North and South Wales. Undoubtedly there are in South Wales very substantial reasons why this is likely to be the case. There is the rapid and uneven growth of population of South Wales, springing from 587,000 in 1801 to 2,013,000 in 1901. If, however, this more than three-fold increase had been evenly spread over Wales it would not have mattered, but half the population of South Wales is living in Glamorganshire, which is only one-ninth of the entire area. Here the augmentation of inhabitants during the last century has been fourteenfold, and no one will be surprised to find that the building of houses has not kept pace with the advent of the new inhabitants. Thus the housing trouble, urgent in all large agglomerations, is specially serious round and about the great iron-works and mining industries of South Wales. The Local Government Board, fully cognisant of the figures, caused a series of special investigations to be made, and some four years ago published many reports on the subject. The chief centre, of course, is Merthyr Tydfil, where a Christian princess named Tydfil was martyred in the sixth century. The church subsequently raised to commemorate this martyrdom has become the centre of a great manufacturing district where many thousands have been brought prematurely to the grave—martyrs to the Moloch of modern industrialism. Indeed, the Merthyr Valley, or the Valley of Martyrdom, is no misnomer, and its sinister appearance does not belie its reputation. It is black, its people are dirty, many have but miserable rags to wear, there is smoke and coal-dust and soot suspended as a pall over the whole scene, while from the centre terrible volcanic eruptions constantly occur that suggest an invasion from the lower regions. It is appalling, but it is also grand, suggesting mighty powers, mastery over the forces of nature, the conquest of the earth and its treasures; but the pity of it is the accompaniment of so much human misery. Why not master the secret of human happiness? Would not this be preferable even to a Bessemer blast furnace?

*A Modern Inferno.*

The story goes that a traveller approaching the Dowlais district of Merthyr asked to be driven back quickly, declaring that he had never before been so near to hell. The word remains. It is no unusual thing for a person to say he has come from hell when he has been to Dowlais. The ironworks for which Dowlais is renowned are situated in a valley, and the hill overlooking them is covered by some of the worst slum dwellings. It was while visiting after dark these hovels where the wealth producers of Dowlais dwell that I was able to contemplate what has so often been compared with the infernal regions. On one side of the works there is a large stretch of open flat ground covered over with rollers that are ever revolving, so that any heavy object placed on them is pushed forward by their rotary action. Formerly these objects required much labour to move; they now glide along as if of their own accord, and the worker who used to manipulate the iron rails is thrown out of employment, his poverty accentuating the housing difficulty. From a fiery region under the Bessemer blast furnace I saw red-hot iron railway lines glide along like great incandescent serpents. Occasionally they pass under an iron structure which squeezes them into a longer and more correct shape, till finally, and as a last ordeal, a steel rotary saw chips off the irregularly shaped tip and tail of the rail. Then the fiery serpent makes a horrible hissing noise and squirts out in all directions, as if it was its life blood, a shower of red-hot iron drops. After that one more glide and the rail has reached its resting-place, where it cools down and loses its bright redness. All this goes on automatically, not a man is to be seen, any amount of work is done, but independently of human labour, while the unemployed clamour at the gates or shiver and starve

in their hovels on the hill close by. Throwing a lurid light over this rapid all-devouring production of wealth and misery the Bessemer blast furnace gives off and illuminates rounded and rolling clouds of pearl-grey smoke and steam. In a little while the colour turns into different shades of yellow, so that the lofty smoke-stack hard by suggests a ghostly, upright, and dignified presiding genius draped in robes of varying tints. Then apparently some sort of cataclysm occurs. A strange darkness comes over the land. The smoke turns to a violet hue, a *lie de vin*, as if the pressed grapes of a vintage had evaporated into clouds that retained its colour. When various chemicals are thrown into the molten metal, so as to purify it, pyrotechnic effects are produced that put exhibitions of fireworks into the shade. And here at least, and close round these Bessemer blast furnaces, men are at work. They can be seen dodging the sparks of molten metal. They grope about, stoop, lift, and run like so many pigmies in the caves of Vulcan. Indeed, the worshippers of this antique divinity never imagined anything so powerful, so huge, grand, and awe-inspiring. But would Vulcan have allowed his assistants to live sordid lives in miserable slums which have acquired such a sensational reputation that the sociological student is told he must not fail to see them? Perhaps if the shareholders of the modern works of Vulcan would also approach the forge and see what the work is like we should not have to wait so long for the much-needed life-saving reforms.

*The "Box and Cox" Problem.*

What these reforms should be is at least in part indicated by Dr. J. Spencer Low's report to the Local Government Board, which was published in the spring of 1906. Some of the more salient points in this report I noted down, and on arriving at Merthyr Tydfil called on the sanitary authorities to inquire whether the criticisms then made still applied. It was gratifying to find that the importance of the housing question is fully recognised. Dr. Alexander Duncan, the medical officer of health, received me most courteously and was very ready to help me in every way. It at once seemed evident that improvements have been effected since the publication of the Government report; but it was likewise equally evident that a great deal still remains to be done. Also in some details there is contradiction in the evidence. For instance, the Blue Book report alludes to the letting of one bed to a couple of tenants, the one being a night worker and the other a day worker. Dr. Duncan doubts whether this was the case when the Government report was written, and does not believe the abuse still exists. On the other hand, when I went about and inquired from different persons who have good opportunities of knowing, they were very positive that the practice still prevailed, and that the farce of *Box and Cox* was being produced any day and in real life at Merthyr Tydfil. What also frequently happens is that when the breadwinner works at night his family occupy his bed during his absence and let their own bed to a lodger. If the bed thus utilised day and night by the family was situated in a large room with big windows, and could have a good airing during the brief intervals between occupancy, the evil might be less obvious. In many cases, on the contrary, it is not even put in what in fairness can be called a room. It is often crowded into a compartment next to the kitchen or living room which is so small that no other furniture but the bed can be introduced. This so-called room may be only 4 feet wide and 8 to 10 feet long. On the hillside, overlooking the ironworks just described, I saw such rooms. They were in little one-storeyed cottages. The door from the street gave on to the one common living room of the house. Here is the fireplace or kitchener where all the cooking is done; here is the square table on which all the meals are served; along one wall is a dresser for the plates, the pots and pans, and most of the possessions of the family When the breadwinner comes home, especially if he is a miner, a tub is rolled up before the fire and a screen placed around it. The man strips for a wash, and his clothes, damp with perspiration and sometimes drenched with rain, are hung up on the screen to dry. Soon the small dwelling is filled with the steam and the human exhalations evaporating from the clothes. By the side of this common room there is the very small compartment where the bed has been placed. If the door to it is closed it will be too cold for the man who has been washing with hot water before a good fire. If the door remains open then the sleeping compartment will be filled with the steam and smells from the kitchen fire and the dirty clothes hanging in front. There may not be a window, a little square opening, barely more than a foot or 18 inches in diameter, giving on to the street and only a few feet above the pavement, will serve instead. And this is not likely to be unobstructed, for mischief-making boys would throw things through and hit the sleeper as he lay stretched under this, the sole aperture giving on to the outer air. Above, under the roof, is one small room, sometimes two. Here the breadwinner and his family might sleep in peace and a better atmosphere, but this they cannot afford, for they must take in lodgers, otherwise it would not be possible to pay the rent.

*Compulsory Cleanliness.*

Another point raised by the Government report was that where back-to-back houses had been abolished by cutting a hole through the partition wall, the letting of the back room as a separate lodging caused the door of communication between the back and the front to be permanently closed, and thus the condition of a back-to-back house was again brought about. The object of such a door is to establish a through draught, but if there are different tenants on each side of the door they will not only keep the door shut, but push whatever heavy furniture they may have against it. The practice still continues, and the effort to do away with back-to-back houses has been frustrated in this manner. Consequently it is now sought to bring such houses under the by-laws as to houses let in lodgings or occupied by more than one family. This, however, is only applied where there are six or more lodgers, and there remain many very insanitary dwellings with a smaller number of inhabitants. Nevertheless, where they can be applied, these by-laws, which are newly enacted, are very stringent and should be effective. They leave little or nothing to the commonsense or to imagination, but minutely define what is meant. Thus overcrowding means less than 400 cubic feet for every person above 10 years of age and 200 cubic feet for every child under that age. Then there must be not more than 12 persons for every closet provided, and the by-law does not merely say that all parts of the premises are to be kept clean; it defines cleanliness as the removal of all slop-water and refuse from within the house at least once a day. The floors are to be swept every day before 11 in the morning and scrubbed every week. The bedroom windows are to be kept open one hour every morning and every afternoon. There is to be a tremendous scouring out of the entire premises with lime-washing of the walls every April and October. The chief point is that this is no mere advice given to housekeepers, but the right of entry and inspection both day and night is carefully secured; and if these rules of cleanliness are not carried out there is a solid penalty of a £5 fine that can be inflicted. It will be found cheaper to sweep and to scrub than to pay £5; and with a certain class of people this is the only way the desired result can be secured. This is excellent so far as it goes; unfortunately, it does not go very far. In the year 1909 there were 11 houses let in lodgings brought under this by-law, but this made a total of only 33 houses in all placed on the register. Some of these houses were put on the register because there were cellar dwellings which, though thrown into communication with the house above, continued to be let to separate tenants. In other cases there were more than six lodgers in the same house paying less than 5*s.* a week for unfurnished, and less than 7*s.* 6*d.* for furnished, lodgings. To see that these 33 houses let in lodgings observed the new by-law 122 inspection visits were paid during the course of the year, yet no contravention was reported. This is very satisfactory so far as it goes, but 33 houses, however clean, is a very small matter in the midst of a population of close upon 80,000 people, this being the estimated population of Merthyr Tydfil.

*(To be continued.)*

A SOMERSET CENTENARIAN.—Miss A. Hutchings, an inmate of Wellington (Somerset) workhouse, celebrated the 100th anniversary of her birthday on Jan. 6th. The father of Miss Hutchings died on the anniversary of his 100th birthday, and her brother died in Australia in his 104th year.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

*Progress of Sanitation in Liverpool.*

THE chairman of the health committee, reviewing the past year from the public health point of view, remarked that for a number of years the returns had shown that the great sanitary operations carried on were slowly but surely bearing fruit. The rate of mortality of Greater Liverpool in 1895 was 24·8 per 1000 of the population. The figure during the succeeding ten years had gradually declined. In 1905 the lowest rate recorded was reached—namely, 19·2 per 1000. In 1909 a further record of 18·3 per 1000 was reached, and for the year 1910 the lowest record of all had been attained—that of 17·4 per 1000—which was eminently satisfactory. It must not be forgotten that the position of Liverpool as a seaport rendered it particularly open to imported disease, whilst the precarious employment incidental to a seaport meant low average wages, much poverty, and its attendant evils. Whilst the infant mortality during the year had been the lowest on record, yet the most marked saving of life had been at the later age-periods. The mortality from phthisis and other forms of tuberculosis had shrunk to a lower figure than previously recorded, and the same observation applied to zymotic diseases generally, whilst for the first time a whole year was passed without one single death from typhus fever. The great saving of life implied by the figures did not by any means represent the full benefit of the improvement in the public health. It was generally calculated that each death represented at least 10 cases of serious and anxious illness. Therefore the diminution in the deaths implied a proportionate diminution in sickness and the suffering and loss inflicted by it. The number of deaths in 1910 was 3000 fewer than in the year of incorporation of the out-townships (1895), notwithstanding that the population had increased by 115,000, which was almost equal to the entire population of Birkenhead. The death-rate was still very high in the Exchange, Scotland, and Everton divisions, in which a good deal of the property was erected quite 100 years ago, when the policy was to get as many houses as possible on an acre of land. In these districts they had to strive to get as many open spaces as possible. If they could effect an improvement in the death-rate in those localities there was no reason why Liverpool should not become one of the healthiest towns in England, and have the lowest death-rate of any seaport in the country. He ventured to prophesy that the death-rate of the city would be gradually reduced to as low a figure as 12·4 per 1000. The returns for the past week showed a death-rate of 17·5, against 18·4 per 1000 last year.

*Liverpool Select Vestry: Epileptic Colony at Maghull; Enlargement of the Liverpool Workhouse; Death of Mr. Henry J. Hagger.*

At a meeting of the select vestry held on Jan. 10th the question of a contemplated expenditure of about £40,000 at Maghull and of over £10,000 on the Liverpool workhouse came up for discussion. The committee appointed to consider the erection of a colony for epileptics at Maghull reported: "Consequent upon the adoption of their first report the committee have considered the further steps to be taken, and now recommend that the proposed buildings be erected at an inclusive cost of the whole not to exceed £150 per bed, or £45,000. The committee considered this a maximum amount, and trust that the architects will find it possible to reduce the cost to about £130 per bed, or £39,000 for the whole. The committee recommended that the architects be engaged by the select vestry to prepare sketch plans of the suggested buildings, together with an estimate of the probable cost of the same. These would have to be submitted to the Local Government Board for their approval before proceeding further." Mr. T. D. Laurence, in moving the adoption of the report, said that the architects had entered into the spirit of the vestry's requirements—good buildings, but inexpensive. The motion was adopted with some slight opposition. It was also agreed to accept a tender for £10,133 for alterations to the Brownlow Hill workhouse, a loan to be applied for in order not to burden the rates too suddenly. In reference to some remarks from members of the vestry that epilepsy was on the decrease, Mr. T. Horrigan challenged the statements, and said that there was an alarming increase of lunatics, imbeciles, epileptics, and kindred sufferers.—The veteran Mr. Henry James Hagger, vestry clerk of the parish of Liverpool, died on Jan. 10th in his eighty-second year. He was the oldest Poor-law official in England, having given 64 years of faithful and capable service to the Liverpool Select Vestry. Prior to interment a memorial service was held in the workhouse chapel, when the bishop of the diocese delivered an impressive address extolling the deceased's many virtues.

*Hospital Sunday in Liverpool.*

On Sunday, Jan. 8th, collections on behalf of the medical charities were made in the various places of worship in the city and suburbs. The amounts were well up to the average, on the whole giving cause for the greatest satisfaction. Ullet-road Unitarian Church rose to the occasion and resumed its place at the head of the list with £575; Sefton Park Presbyterian Church was a good second with £528. The total amount collected since 1871 (the year of foundation) realised £463,769, which was distributed among the various hospitals, minus £19,000, expenses incurred. The expenses of the committee have not been guaranteed this year as on one or two former occasions.

Jan. 17th.

## BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

*Tuberculosis in Bristol.*

AT the request of the health committee of the Bristol city council, Dr. D. S. Davies, the medical officer of health, has prepared an interesting report on tuberculosis. Much of it consists of general information, and though this will be of great value to the laymen who read it, the principal interest as far as the medical profession is concerned lies in those parts of the report which relate to the incidence of tuberculosis in Bristol. In one table the decline of the phthisis mortality is strikingly illustrated; in 1856 the death-rate from phthisis was 269 per 100,000 living, while in 1909 it was only 103, and the years intervening show that the decline has been a steady one. Dr. Davies estimates that at the end of 1909 there were 2552 persons with phthisis living in Bristol, and that under the voluntary system of notification at present in force almost half the cases which occur escape notification. The risks of overcrowding are most quickly lessened by removal of the sick from among the healthy, though, of course, every means should be used to diminish overcrowding itself. The factors which have been responsible for the decline of tuberculosis in Bristol are general improvement in sanitation and housing, dissemination of knowledge as to the nature of the disease, institutional segregation (as in the workhouse infirmaries), sanatorium treatment at Winsley, notification and the control thus acquired by the health officer over the spread of the disease, increased care with regard to food supplies, and pamphlets of advice. The institutional treatment at present available for patients suffering from phthisis in Bristol is represented by 20 beds maintained by the corporation at the Winsley Sanatorium and the provision made by the Poor-law authorities. The work done by the 20 Winsley beds in the past five years is summed up in the statement that of 866 applications for admission it has been possible to receive 357, of whom about half retained working capacity at the end of the period under consideration. The number of rejections with that of the non-recoveries makes it clear that the provision made by the corporation needs to be supplemented by some such means as a farm colony. Further accommodation is also needed for advanced cases; the guardians have done a good deal in this direction and are considering further steps. In concluding, Dr. Davies recommends the following measures as an expansion of the good work already in progress: reissue of handbills concerning alcoholism, by-laws for the artificial elevation of low or damp sites, provision of public abattoirs, strengthening of supervision over meat and milk supplies, systematic examination annually of milk for tuberculosis, compulsory notification, health visitors and nurses,

reissue of pamphlet advice, more sanatorium beds for early cases, farm colonies for after-treatment, more institutional accommodation for advanced cases, and antituberculosis dispensaries.

*University of Bristol Colston Society: Annual Dinner.*

The twelfth annual dinner of members of the Colston Society was held on Jan. 16th in the large hall of the University, under the presidency of Mr. J. H. Howell. The guests of the evening were Sir Alfred Hopkinson, K.C., LL.D., and Sir Thomas H. Elliott, K.C.B. The treasurer of the society, Mr. J. W. Arrowsmith, was able to announce a collection of £628, which will be devoted, as in preceding years, to the support of the University. The present aim of the society is to raise £1000 a year for the endowment of a Colston chair. The health of the guests was proposed by the Bishop of Bristol. Sir Thomas Elliott, responding first, emphasised the pre-eminent importance of agricultural research such as is contemplated under the auspices of the society, and by means of its contributions to the University. Sir Alfred Hopkinson, who followed, spoke of the great value of the new universities to the nation, and of the close union which ought to exist between citizens and university in a city like Bristol. He urged the citizens to maintain the University in a condition of independence, and not to allow it to become attached to a department of State. Dr. R. Shingleton Smith proposed "The City of Bristol," to which the Lord Mayor and the Sheriff replied. In response to the toast of the University, proposed by Sir W. Howell Davies, Sir Isambard Owen, the Vice-Chancellor, said that he hoped the University would have money enough to build itself an adequate library, to provide itself with a sufficient stock of scientific apparatus, and to support the research carried on within its walls. In conclusion Mr. Howell introduced Sir Isambard Owen as the president-elect.

*Bristol University Settlement.*

The scheme which has for long been under discussion is gradually issuing from the realm of mere discussion and project into that of fact. The settlement which is to be established under the auspices of the University will be, in the first instance, a women's settlement—that is to say, the first set of residents will be women, though men will help in the work. The site chosen is in Barton Hill, a large overcrowded district of working-class streets, consisting of dwellings too recently built to be classed as "slums," but housing a class to whom such work must be beneficial in the highest degree. The settlement, which is to be started in the autumn, will be supported by private contributions and not out of University funds. Workers will be supplied by the University, and the task of organisation will fall upon the University.

*Improvement of Housing in Bristol.*

The Bristol city council has determined to sweep away an area of slum dwellings in St. Philip's which has long been an eyesore to persons arriving in the city by train from the eastern side. It is probable that this will displace a population of 600 or more. Provision of fresh accommodation for these persons is no part of the scheme passed by the council, but it is hoped that the share which Bristol is to receive of the Sutton bequest will facilitate the erection of model dwellings. Under the will of the late Mr. W. R. Sutton £500,000 have been allocated for the acquisition of sites and building of model dwellings in two poor districts of London and eight provincial cities, of which Bristol is to be one.

*Bristol Dispensary.*

At the annual meeting of the Bristol Dispensary it was stated that the number of new patients admitted to treatment in 1910 was 11,774, an increase of 681 over the previous year. The number of midwifery notes issued was 688 and medical assistance was called for in 31 confinements. The balance-sheet shows that the income exceeded the expenditure, though by a smaller margin than in the preceding year. An old house which used to be the dispensary has been disposed of for £750 and several legacies and donations were also received. There have been two changes in the staff—Dr. C. E. K. Herapath and Mr. T. B. Dixon succeeding Dr. W. J. H. Pinniger and Dr. J. F. Blackett, both of whom have resigned.

*Case under the Midwives Act.*

At the Gloucester police-court on Jan. 7th, Susannah Longney of Norton was fined £1 and 6*s.* costs for unlawfully using the title of midwife, she not being certified under the Midwives Act. The woman displayed a board stating that she was a midwife, after the Central Midwives Board had notified her that her name had been removed from the roll of midwives. This is one of the first cases instituted in Gloucestershire under the Act.

*Enlarged Public Health Laboratory for Somerset.*

At a meeting of the Somerset county council, recently held at Taunton, it was decided, on the advice of Dr. W. G. Savage, medical officer of health, to extend the public health laboratory by setting apart two rooms in the county council office at Weston-super-Mare for that purpose. The cost of furnishing the rooms will be £120, and the estimated expenditure will be about £250 per annum, which will include the salary of the analyst of £200. No fees will be charged for public health work to boards of guardians, district councils, borough sanitary authorities, &c., and the medical officer of health will arrange a scale of charges for other authorities and persons.

*Proposed Hospital for Burnham and Highbridge.*

The Burnham and Highbridge (Somerset) district councils are unofficially supporting the proposal for erecting a cottage hospital for the districts of Burnham and Highbridge, and a public meeting will shortly be called to consider the matter. A small hospital is much required, and the medical men of the neighbourhood are strongly in favour of the scheme.

*The Plymouth Memorial to King Edward VII.*

At a public meeting held in Plymouth on Jan. 5th it was decided to establish a "King Edward Fund" as a memorial to the late King. An influential committee was appointed to raise funds for the purpose. It was also determined that the sum of money thus raised "should be devoted to the prevention and cure of consumption in Plymouth in such manner as the committee may decide."

*Medical Relief and Old-age Pensions.*

At the meeting of the St. Thomas's (Exeter) board of guardians, held on Jan. 13th, the chairman suggested that the district medical officers should be informed that, except in cases of emergency, they were not to attend any old-age pensioners without a note from the relieving officers.

*The late Deputy Inspector-General Matthew Coates, M.D. Durh., F.R.C.S. Eng., L.S.A., R.N. (retired).*

Deputy Inspector-General M. Coates died at his residence, Bursledon House, Dawlish, Devon, on Jan. 13th, after a short illness. The deceased officer received his medical education at the Bristol Medical School, and he also studied at Paris. He took the M.R.C.S. qualification in 1859, and the year following the L.S.A. In 1869 he passed the examination for the F.R.C.S., and graduated M.D. of Durham in 1883. Shortly after qualifying he entered the Royal Navy as assistant surgeon. From 1863 to 1865 he was assistant surgeon at the Royal Naval Hospital, Haslar, and from 1867–71 he held a similar appointment at H.M. Dockyard, Devonport. From 1875 to 1878 he was staff-surgeon in charge of the Royal Naval Hospital, Esquimalt, Vancouver Island. In 1882 he retired from the service, with the rank of deputy inspector-general. He shortly afterwards came to Dawlish, where he soon became very popular. He was much interested in ambulance work, was a lecturer and examiner for the St. John Ambulance Association, and an Honorary Associate of the Order of St. John of Jerusalem.

*A Cottage Hospital for St. Austell (Cornwall).*

At a meeting held at St. Austell last week it was decided to erect a cottage hospital which will contain 10 beds. The hospital will be only used for accident cases. Up to the present nearly £2000 has been raised, and the committee requires £600 more. It is hoped that the foundation-stone of the building will be laid early in April and that the institution will be finished in six months.

*The late Dr. George Morton Wilson.*

A memorial has been erected at Pendyffryn, by several old friends and patients, to the memory of the late Dr. G. Morton Wilson. The memorial, which was unveiled last week, is a handsome sundial. It contains four medallions, one of which is a portrait of Dr. Wilson; the other three have symbolic figures of a lion, ox, and pelican. Dr. Wilson's motto "Hasten slowly" is also inscribed. Dr. Wilson was a Cornishman, his father, the late Dr. George Wilson, having

practised for many years at Launceston. Dr. Wilson, who established the Nordrach-in-Wales at Pendyffryn, was one of the first to recognise the importance of the sanatorium treatment for pulmonary tuberculosis. He died at Pendyffryn on Jan. 6th, 1910, in his forty-fourth year.

Jan. 17th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Irish Emigration Statistics.*

THE report of the Registrar-General of the number of emigrants, natives of Ireland, who left Ireland during the month of December, 1910, shows that the total number was 423, as compared with 633 in the same month in 1909, a decrease of 210. The total number of emigrants for the year was 32,457, as compared with 28,676, an increase of 3781. Of this total 4258 were from Leinster, 8330 from Munster, 12,271 from Ulster, and 7598 from Connaught. 24,905 of these went to the United States, 4416 to Canada, 165 to South Africa, 613 to Australia, 179 to New Zealand, and 83 to other countries; 1656 went to England and Wales, 440 to Scotland, and of the 22,639 steerage passengers to the United States 7263 had their passages paid for in America. Two years ago, in the period of financial depression in America, the number of emigrants from Ireland suddenly dropped by about 40 per cent. Each year since, however, shows a gradual return to the previous average.

*Dublin Joint Sanatorium.*

It is hoped that the Consumptive Sanatorium of the city and county of Dublin may be ready for occupation at an early date. Nearly all the sanitary authorities of the county and city have united for its establishment, and a convenient and suitable site, on the western slope of the Dublin mountains some nine miles from the city, has been chosen. Building operations have been going on for some time. In the selection of a medical superintendent the joint committee adopted a wise plan, which one would gladly see adopted by other local authorities in the choice of medical officers. A committee of experts, consisting of the Presidents of the two Royal Colleges and the professors of medicine in the two universities situated in Dublin, was invited to consider the applications of all the candidates and to advise as to the best appointment. The expert committee selected out of a large number of applicants the four most suitable candidates. The joint committee elected the gentleman, Dr. Blake, whose name appeared first on the list.

*Deadlock in Skibbereen Union.*

For the past 12 months there has been a deadlock regarding the appointment of a medical officer for the Skibbereen union hospital. When Dr. W. Jennings died the board of guardians advertised the vacancy, and when the day of election came, elected two medical officers. The Local Government Board, while admitting its willingness to sanction the appointment of two medical officers, actually gave approval only to the appointment of Dr. T. J. O'Meara, declaring that Dr. P. J. Burke had been elected without due notice. The guardians brought the matter before the King's Bench, where it was decided that the election was invalid. All this took place several months ago, but as yet no election has taken place. On one occasion when notice had been given of intention to elect, the chairman refused to receive nominations, and summarily adjourned the board. Last week, under threat of a mandamus from the Local Government Board, the guardians proceeded to election, but the board being equally divided the election again fell through.

*Tyrone and Fermanagh Asylum.*

At the monthly meeting of the committee of management of this asylum, held on Jan. 12th, a resolution was adopted in favour of urging the Government to make provision for an annual grant of a fixed sum per head of not less than 4*s.* per week, the total contribution to any one district to increase or decrease as the numbers of lunatics increase or decrease, and deprecating the present system of deducting repayment of loans from the annual expenditure in calculating the annual cost per head for the purpose of the 4*s.* grant as being most unfair to the local ratepayers and in contravention of the Act of 1898.

*Monaghan and Cavan Asylum.*

At a meeting of the joint board of management of this asylum, held on Jan. 12th, it was reported that at present there were in the institution 918 patients, of whom 416 were chargeable to Monaghan and 502 to County Cavan. As to their estimates for next year there was an increase of £2000 on that of the previous year, which meant an increase of 1*d.* in the £.

*Glenties Workhouse.*

Mr. J. Coffey, Local Government Board inspector, has reported that, while no part of Glenties Workhouse Co. Donegal) could perhaps be quite classed as dirty, yet, with the exception of perhaps two wards, no part of it could be classed as clean. The report is to be considered by a committee of the guardians.

Jan. 17th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*Edinburgh Royal Infirmary.*

THE annual report of the managers of the Edinburgh Royal Infirmary has been submitted to the General Court of Contributors. The total number of patients treated as in-patients during the year was 12,342, as against 12,388 in the preceding year. The average daily number of patients was 842, as against 845; the average daily number of children was 85, as against 80; the largest number of patients on any one date was 881, as against 878; and the average period of residence was 25·1 days, this figure being the same as in 1909. Of the cases admitted, 5691 came from Edinburgh, 469 from Leith, and 5363 from the country. In the out-patient department 38,930 patients were treated, most of whom attended several times. The total ordinary income was £36,129 3*s.* 11*d.*, an increase of £301 8*s.* 11*d.* on the income of the previous year. The ordinary expenditure amounted to £54,217 17*s.* 2*d.*, an increase of £428 12*s.* 3*d.* The entire ordinary expenditure during the year (including the out-patient departments) per occupied bed was £64 7*s.* 10*d.*, an increase of 14*s.* 8½*d.* on 1909. There was a decrease in maintenance per occupied bed of 2*s.* 0½*d.*, but an increase in medical expenditure of 7*s.* 1*d.* The legacies and donations of £100 and upwards to the general funds amounted to £24,123 14*s.* 6*d.* There were 745 applications for admission as compared with 784 in 1909. The average number of nurses and probationers during the year was 260, The question of the remuneration of the sisters had been the subject of inquiry during the year. It was resolved that instead of increasing the pay, the retiring pension should be raised and that in future no payment on account of premiums should be required from the sisters. Hitherto the retiring allowance has been an annuity of £25, each sister having to pay a one-fourth share of the premium. The principal new works carried out during the year included the enlarging of the nurses' dining-room with the addition of a large pantry and scullery, and the providing of additional accommodation for nurses and female servants in Archibald-place. The Clinical Medicine Laboratory, the gift of an anonymous donor, was completed and formally opened by Sir Clifford Allbutt on Oct. 13th, 1910. The managers record their regret at the loss sustained by the infirmary by the death of Dr. Claud Muirhead, whose services to it had extended over 40 years, since he became an assistant physician in 1869. They also record with regret the death of Dr. John Smith, who had been consulting dental surgeon since 1888, having served for 25 years as dental surgeon to the infirmary.

*Montrose Asylum Management.*

A meeting of the managers of Montrose Asylum and Infirmary Board was held on Jan. 10th, when a communication was read from the Secretary of State for Scotland with reference to the proposed changes in the constitution and management of the asylum. Lord Pentland stated that he had had under further consideration representations made to him and to his predecessors by the Forfar District Lunacy Board and the parish councils of the counties of Forfar and Kincardine, in support of a proposal to effect

changes in the constitution and management of Montrose Royal Asylum, and also the proposals made for the new charter put forward by the managers of the Asylum Board. His lordship was aware that the new charter, as outlined in these proposals, was not viewed by the district lunacy board and parish councils as sufficiently meeting the necessities of the case, but he recognised the desire which these proposals evidenced on the part of the asylum managers to arrive at a settlement of the question at issue. It appeared to him that these could be discussed at a conference of the managers and representatives of the district lunacy board and representatives of the parish councils, and progress made towards this end. It was agreed to hold a meeting in about a fortnight to consider the matter. The question also came before a meeting of the Forfar District Lunacy Board at Forfar on Jan. 9th, to whom the Secretary for Scotland had also replied in similar terms. The board agreed to the proposal contained in the letter and resolved to appoint three of its number to attend any conference which might be held regarding the matter.

*Aberdeen Parish Council: Medical Officer Question.*

The Aberdeen parish council has at last settled the vexed question of the medical officership of Oldmill Poorhouse. In last week's issue I reported that the poorhouse committee recommended to the council the appointment of a visiting medical officer at a salary of £150 per annum. The council met on Jan. 10th, and after a long discussion rejected this recommendation, and decided by 17 votes to 10 to appoint a male resident medical officer at a salary of £200 per annum with board, at the same time retaining the services of the present lady resident medical officer at a salary of £90 per annum.

*Hospital Sunday in Aberdeen.*

Hospital Sunday fell on New Year's Day, and as the weather was bad the collections in a good many churches were poor. In other cases, however, it is gratifying to note an increased liberality, while in one or two cases the collection was postponed. The total for 44 churches and meeting places was £746 2*s.* 6*d.*, as against £924 12*s.* 8*d.* for 51 churches last year. The United Free Church comes first with £365 6*s.* 11*d.* for 16 congregations; the Church of Scotland next with £268 14*s.* 5*d.* for 12 congregations; five Congregational churches contribute £47 17*s.* 4*d*; three Baptist churches, £8 2*s.* 1*d.*; six Episcopal churches, £15 10*s.* 9*d.*; two Roman Catholic churches, £33 3*s.*; and six other churches and services, £7 8*s.*

Jan. 17th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Penetrating Wound of the Liver by a Bullet entering the Chest.*

AT a meeting of the Surgical Society held on Jan. 11th, M. Potherat showed a youth, aged 15 years, who had received a revolver bullet in his right thoracic region. He did not at first present any symptoms giving cause for alarm, but after some hours there were evident signs of internal hæmorrhage. Careful examination of the thorax proved that the heart and lungs were uninjured; there was, however, marked retraction of the abdominal wall which made it probable that the abdominal contents had suffered. Laparotomy disclosed an extensive effusion of blood under the liver proceeding from a perforating wound of that organ; the point of entrance, which was small and situated on the upper surface of the liver, was not bleeding, but the point of exit, which was very large and situated on the inferior surface of the right lobe, was bleeding profusely. M. Potherat, after removal of the effused blood, closed the aperture in the lower surface of the liver with five sutures of stout catgut, and when the hæmorrhage was arrested he proceeded to search for the bullet. Without causing any further important injury it had traversed the root of the mesentery, and, passing under the peritoneum, had buried itself in the posterior wall of the abdomen on a level with the insertion of the right psoas muscle. Radiography afterwards showed it in this position, but M. Potherat did not think that its extraction was necessary. The patient had recovered completely.

*The Question of Depopulation.*

At a meeting of the Société de l'Internat des Hôpitaux de Paris held on Dec. 22nd, 1910, M. Créquy said that one factor in the question of depopulation was the circumstance that midwives, induced by the commissions offered by the registry offices, advised mothers to put their children out to nurse on the pretext that the mothers' health did not permit them to suckle their children. The mortality of bottle-fed infants was, however, five or six times as great as that of breast-fed infants. Statistics also showed that cases of abortion induced by midwives were very numerous. The remedy for this state of things was to give midwives the status of public officials—a system which would have the effect of distributing them uniformly over the whole of France. M. Bouchacourt, continuing the discussion, said that midwives who suffered from the overcrowding of their occupation in large towns were tempted to make money by questionable practices.

*Fire at the Hôpital Bichat.*

About 2 A.M. on Jan. 14th a fire broke out in the salle Louis of the Hôpital Bichat, a room which is on the ground floor of the building and is used as a store for the clothing of deceased patients. There was immediately a serious panic among the patients in the wards. Those who were able to do so made their escape, hardly giving themselves time to put on their clothes, while those who could not leave their beds uttered piercing cries. The firemen at the Carpeaux barracks on receiving a call hastened to the scene and dealt energetically with the fire, which threatened to spread to a pavilion filled with patients. After half an hour's work all danger was at an end and calm was restored. The origin of the outbreak has not yet been traced.

*Ehrlich's New Remedy "No. 606" in Diseases of the Eye.*

At a meeting of the Academy of Medicine held on Jan. 10th M. de Lapersonne and M. André Léri discussed the effects observed when patients suffering from diseases of the eye were treated with Ehrlich's antisyphilitic remedy, "arsenobenzol." They commenced with the statement that this arsenical compound had a much less injurious action on the visual organs than those which had hitherto been employed in syphilis. Atoxyl, for instance, has caused serious injury to the eye, even to the extent of producing blindness, but arsenobenzol, being more rapidly eliminated and not being given at such short intervals as atoxyl, was much less harmful to the eye. In the hands of M. de Lapersonne and M. Léri arsenobenzol had given good results in cases of iritis and even of optic neuritis without occasioning any concomitant ill-effects. In common with other observers they had found that a single injection of arsenobenzol did not bring about radical and permanent recovery from syphilis; relapses were, in fact, not infrequent, and Ehrlich himself had at last become an advocate of repeated injections. The remedy was unquestionably very powerful, very rapid in its action, and produced effects which could be more easily observed from day to day in cutaneous lesions than in the case of the eye. The new treatment might be combined with the use of mercurial remedies, which had not lost any of their therapeutic importance.

*A Conviction for Illegal Practice of Medicine.*

An unqualified practitioner, well known as the "Zouave" Jacob, who is at present 85 years of age, was last year acquitted by the Tenth Chamber of the Correctional Tribunal on a charge of the illegal practice of medicine. At the instance of the prosecution the case came before the Appeal Court on Jan. 14th. In his defence Jacob said that he was an intermediary between healing spirits and patients, and that he received a healing fluid which he therefore imparted to sick persons for the purpose of curing them. Notwithstanding this plea the court convicted him of illegal practice of medicine, ordering him to pay a fine of 100 francs and 200 francs damages to the Syndicate of Medical Men of the Seine. In pronouncing judgment the court gave an interesting definition of the word *traitement*, declaring that this word, which must not be used by a person unprovided with a medical diploma, includes whatever is done or advised for the recovery of a sick person or the relief of his symptoms.

Jan. 17th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

*Intravenous Injection of Grape Sugar.*

Professor Kausch of Schöneberg, writing to the *Deutsche Medizinische Wochenschrift*, mentions that he has administered a solution of grape sugar by subcutaneous or intravenous injection to patients who could not be fed in the natural way. He has found that subcutaneous injections of strengths varying from 2 to 5 per cent. or intravenous injections of strengths varying from 5 to 7 per cent. of grape sugar were well tolerated by patients in a quantity of 1000 cubic centimetres per diem. Sugar was excreted by the urine after repeated injections, but only to the extent of 2 or 3 per cent. of the quantity administered. No undesirable complications ensued —neither pain, nor thrombosis, nor interference with the heart or other organs. Intravenous injection was preferable to the subcutaneous method, because by the former a larger quantity of fluid and that in a state of greater concentration could be administered. The sugar must be dissolved in a solution of sodium chloride of 0·9 per cent. strength, then filtered, and finally boiled; for intravenous injections from four to eight drops of a solution of adrenalin of 1 per 1000 strength must be added. With regard to the effect of the grape sugar on nutrition, Professor Kausch stated that the worse the state of nutrition of a patient was, the larger was the quantity of sugar that could be tolerated. He mentioned the case of a woman suffering from puerperal septicæmia in whom a temperature of over 40° C. was associated with vomiting and diarrhœa. She was given intravenous injection of grape sugar once or twice a day until 2000 cubic centimetres of a 9 per cent. solution were injected daily, only from 0·2 to 0·3 gramme of sugar was excreted by the urine, and in the result the patient recovered. It was very likely that the remainder of the sugar which did not make its appearance in the urine was assimilated by the organism; in this way food having a calorific value of 500 might be introduced into the organism each day. Cane sugar administered in the same way was also tolerated, but the proportion of it excreted in the urine was larger than in the case of grape sugar. Professor Kausch said that up to the present time it had not been known that the human organism was capable of assimilating such large quantities of sugar, and that this circumstance was not yet taken advantage of for the purpose of feeding patients. Although he had employed the method for surgical cases only, he was of opinion that it would be valuable also in the treatment of various ailments in which feeding in the natural way was difficult, especially in the hyperemesis of hysteria and pregnancy, in diseases of the gastro-intestinal canal, and in cholera. In the latter cases the injection of a solution of grape sugar was more efficacious than the injection of a solution of chloride of sodium.

*Statistics of the Medical Profession.*

According to the Medical Directory, edited by Professor Schwalbe, the number of medical men in Germany is 32,449, showing an increase of 480 over last year. There are now 5·01 medical men for each 10,000 of the population, which means a small decrease of the proportional number since the two previous years, in which it was 5·02 and 5·06 respectively. An increase of the medical profession may be expected in the near future, as the number of medical students has risen rapidly from 6032 in 1905 to 11,125 in 1910. It must, however, be remembered that this number includes the foreign medical students, of whom only a very small number pass the State examination and settle in Germany. The number of qualifications granted, which was 553 in the academical year 1906–07, rose to 829 in 1907–08, and to 942 in 1908–09. With respect to the distribution of the profession in the different parts of the Empire, it is remarkable that the recent statistics show a general increase throughout nearly the whole Empire (Mecklenburg, Saxony, and Alsace-Lorraine excepted); in the previous year the increase concerned only the western and southern parts, whilst in the eastern parts a small decrease was recorded. The large cities continue to be preferred by the profession. Of the 480 medical men who settled in practice last year, 329 reside in the large towns of over 100,0000 inhabitants; and of the 32,449 medical men practising in Germany, 13,261 reside in those large towns. For each 10,000 inhabitants of the large towns there were 9·85 medical men (in Berlin alone 12·32); for each 10,000 of the smaller towns and the country the corresponding proportion was 3·74. The number for the large towns has slightly decreased, while that for the smaller towns and the country has been the same as in the previous year. Of the large towns, Wiesbaden as a watering-place and health resort has far the greatest number of medical men—namely, 22·6 for each 10,000 inhabitants; next in order comes Munich with 16·6 per 10,000 inhabitants; whilst the town of Gelsenkirchen, in the Westphalian mining district, has the lowest number—namely, 4·0 for each 10,000 of its population of 180,000 inhabitants. The number of medical women, which was 55 in 1908 and 69 in 1909, has risen greatly, being now 102, of whom 32 are in Berlin. With regard to female medical students, 512 were registered, as compared with 379 in the previous year, foreigners being, of course, included. The number of specialists, which in 1906 was 6258—i.e., 20·2 per cent. of the profession—has risen in 1910 to 7272—i.e., to 22·4 per cent. of the profession. Of the specialists, those for diseases of women are the most numerous, then come the ophthalmologists, and in the third place specialists for diseases of the ear, the nose, and the larynx. Of the large towns, Dresden has relatively the greatest number of specialists, the proportion being not less than 44·2 per cent. of the profession. The figures have been analysed by the well-known statistician, Dr. Prinzing.

*Treatment of Malignant Growths.*

At a recent meeting of the Verein für Innere Medicin Dr. Reicher showed cases in which malignant growths had been treated by injections of adrenalin. He said that he had first administered this substance to rats and mice suffering from sarcoma and carcinoma, the result being that the animals recovered. In the human subject he had used adrenalin only in advanced cases, but a decrease of the growth and of the enlarged lymphatic glands was, however, obtained. In a boy, 12 years of age, suffering from a chondrosarcoma of the skull, the growth decreased to one-third of its original size after daily injections continued for 25 days; the boy also in that time gained 5 pounds in weight. The residual growth was then subjected to currents of high frequency, and finally to Roentgen rays, with the result that it disappeared two months ago. He had obtained a progressive metamorphosis in five cases of malignant growth, and he showed to the society a patient in whom a carcinoma of the skull, having, he said, the size of a gourd, had disappeared one and a half years ago.

Jan. 16th.

## ITALY.

(FROM OUR OWN CORRESPONDENT.)

*Law and Medicine.*

THE "Third Italy" has just opened, in the presence of Royalty and with every accessory of solemn inauguration, her Palace of Justice on the right bank of the Tiber, and the event coincides with the resuscitation of controversy as to the delimitation of frontier between the sister professions, Law and Medicine. These are continually overlapping, with more or less friction, particularly in criminal trials, throughout Italy, and, truth to tell, when they come into actual conflict the palm is apt to rest with the medical combatant, who, if he does not gain absolute victory, invariably receives a cession of territory which puts him at fresh advantage in the next encounter. The medico-psychological witness is treated with a respect, not to say deference, rarely accorded him in transalpine tribunals, where the presiding judge has been known to warn the jury that if the combined colleges of physicians in Christendom told them that a man might, physically, be so impelled to crime that, with full knowledge of the penalty he was incurring, he could not control the impulse to commit it, they were to attach no weight whatever to the deposition. Such intervention, in such a sense, would now be impossible in Italy, where medico-psychology, progressing on inductive lines and appealing to an exhaustive *catena* of cases drawn from clinical experience, has relegated to the criminal asylum offenders who, in a

previous generation, or countries ruled by tradition rather than by science, would have been dealt with as "responsible" and punished accordingly.

*The Effects of Solitary Confinement.*

That life-long incarceration, as a substitute for the death penalty, is fraught with evils *per se*—evils which make hanging or beheading seem humane in comparison—is a conclusion to which Italians, with more or less reluctance, are coming round. The frequency with which the inmate of the solitary cell, to which he is condemned till the close of his days, relapses into decrepitude physically and into idiocy mentally, when he does not "solve the problem of existence" by suicide, is manifestly impressing the public, and, coincidently, the forensic or judicial mind—impressing it, moreover, with a force which may one day lead to a resumption of the methods which it has prided itself on abandoning. True, the brutal, degrading scenes accompanying the revival of public executions in France—the guillotining of Favier at Lille the other day being an instance in point—tend to give pause to the movement in favour of the death penalty. But, on the other hand, the system adopted in the British Isles, reported and commented on throughout Italy on the occasion of Crippen's execution, is cited in abatement of the arguments based on French example, insomuch that if Italy returns to her practice of 40 years ago it will be on the lines of British precedent. As I write a deplorable case of suicide in prison "*per mancanza di compagnia* (for want of company)" is reported from Nice, where the criminal, on being denied human intercourse with his fellow prisoners, hanged himself (like Luccheni and Bresci and so many other assassins) by suspension from the grating of his cell. Why, Italians are asking, refrain from anticipating by the short, sharp British practice the method clumsily adopted after days or weeks or even years of suffering by the criminal himself?

*The Countess Tarnowska.*

In this context, the prison life of the protagonist in the trial which at Venice in the spring of last year fascinated the attention of all Christendom has an interest of its own. The Countess Tarnowska is now causing the gravest solicitude to the prison authorities by a succession of convulsive fits, followed by insomnia of a persistent type and visitations of panic, culminating in persecution mania. In dread of being poisoned she refuses to eat, even to smoke, resists being put to bed, and bivouacs on the floor. Pending the appeal to the Court of Cassation she used to learn Italian, to practise on the piano and the harp, and to exercise her vocal gifts in singing. Since that appeal has been rejected she has developed the symptoms above referred to, and now, by the intervention of the Government, she will be removed to the "carcere giudiziaria" (judicial prison) at Genoa, there to undergo special treatment at the hands of Dr. Luigi Maria Bossi, professor of gynæcology, with special experience in cases of hysteria. From first to last the countess has been a more interesting subject to medicine than even to the law, and the official report of her response to the new treatment awaiting her will be read with peculiar interest, not in Italy only, but wherever neuroses, fostered by stimulants, narcotics, and the unbridled sway of the passions, have run a continuous course.

Jan. 14th.

## UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

*The Census of the United States.*

THE census of the United States, the results of which have been recently published, presents many points of interest. The total continental population of the country is now 91,402,151, an increase of 15,977,691 over the population of 1900. The increase for the past decade is greater than for that of the previous ten-year period, due, it is stated, to greater net additions to the population by immigration. The natural increase has been probably somewhat less from 1900 to 1910 than it was from 1890 to 1900. An instructive feature of the report is the far more rapid growth of the cities than of the rural districts. In the north the proportion of the total city-dwelling population was 40·6 per cent. in 1910, 34·2 per cent. in 1900, and 28·6 per cent. in 1890. In the south the corresponding percentages were 12·8 per cent. in 1910, 10·1 per cent. in 1900, and 9·5 per cent. in 1890. In the west the proportion living in cities of 25,000 inhabitants or more was 31·5 per cent. in 1910, as compared with 25·2 in 1900 and 22·6 per cent. in 1890. In short, 44·5 per cent. of the increase of the population of the United States from 1900 to 1910 has occurred in cities having 25,000 inhabitants or more. In the rural districts there has been, in many counties throughout the country, an absolute decrease of population. The director of the census returns is of opinion that this decrease is due not entirely to movement to the cities, but in some districts to movement to newer agricultural regions. The States that show the greatest increase of population, an increase of from 20 to 30 per cent., during the past ten years are for the most part the great manufacturing States of the north-eastern section of the country, including Massachusetts, Rhode Island, Connecticut, New York, Pennsylvania, and West Virginia. The only other States that have increased between 20 and 30 per cent. are Arkansas and Texas. As in Europe, so in America, the trend of population is to the towns.

*A National Organisation for the Prevention of Blindness.*

At a conference held in New York on Dec. 17th a national society for the prevention of blindness and conservation of vision was organised. Dr. Park Lewis, of the American Medical Association's committee on the prevention of blindness, Mr. Edward M. Van Cleve, President of the Ohio Commission for the Blind, and Mr. James P. Monroe, President of a similar commission in Massachusetts, were responsible for summoning the meeting. The committee on organisation recommended that the society include all persons and public bodies desirous of coöperating in "prevention of infantile blindness, prevention of blindness from industrial and other accidents and from disease, and conservation of vision through improved hygiene during school life and in industrial occupations," and that it invite the coöperation of prevention societies now in existence, of State and national medical societies, educational bodies, labour organisations, commercial bodies, women's clubs, and the like. On the motion of Dr. Studdiford of the New York Board of Health it was resolved that measures be taken to secure State legislation for the training, registration, licensing, supervision, and control of midwives, for the reason that half the births in cities are attended by such women, many of whom are ignorant, untrained, and incompetent, and that unnecessary blindness, mental and physical degeneracy, and suffering or death of mothers, are among the results of obstetrical malpractice. Mr. H. F. J. Porter, a consulting engineer who, according to accepted report, was one of the first to examine swimming-baths for their infectious possibilities, said that many infected eyes were due to the infrequency of the change of water in public swimming-baths and in pools, in gymnasiums, and factories. Another speaker called attention to the menace of the cheap spectacles which are now so largely sold. Increased scrutiny of trachoma among immigrants and examination of lighting facilities in public schools were also considered. The project to create a national organisation in the United States for the prevention of blindness is said to have received the approval of many of the leading ophthalmologists of the country.

*Prevention of Infant Mortality.*

A convention on infant mortality was held in Baltimore recently by the American Association for the Study and Prevention of Infant Mortality. The death-rate of infants under one year of age is very large in the United States. At the meeting in Baltimore the conditions tending to affect adversely the health and lives of very young children were exhaustively discussed. The question of milk in particular was debated in all its bearings, as well as the necessity for instructing mothers of the working class in the proper methods of rearing infants.

*Health of Panama and District.*

According to the recent report of the Panama Department of Sanitation, the total number of deaths among employees in the Canal Zone during October last was 42, 23 being from disease and 19 from injuries, making an annual death-rate per 1000 of 10·19. This rate is somewhat higher than that

for October, 1909. The annual average death-rate during October of this year in Panama, Colon, and the Canal Zone, and including the entire population, was 23·6. This, again, is an increase on the rate of the previous year. It is explained by the fact that there were a larger number of deaths from intestinal disorders among infants in the city of Panama.

*Investigation of Typhoid Fever at the Naval Academy at Annapolis.*

The Secretary of State has appointed a board of inspection to investigate the recent epidemic of typhoid fever at the Naval Academy at Annapolis.

*Gaynor Hospital Fund.*

A sum of $15,180 (£3036), collected as a thanksgiving offering for Mayor Gaynor's recovery from the injury inflicted by his would-be assassin, has been presented to the sisters in charge of St. Mary's Hospital, Hoboken, the institution in which the mayor was treated. £1000 will be devoted to the endowment of a bed to be known as the "Gaynor bed," and the remainder will be handed over to the hospital authorities.

Jan. 12th.

## NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

*Plague.*

THERE was a slight increase in plague mortality during the week ending Nov. 19th, the figures being 7932 seizures and 6106 deaths, against 7305 and 5359, the respective figures of the preceding week. The provincial figures were: United Provinces, 1298 deaths; Bombay, 857; the Punjab, 840; the Central Provinces, 780; Rajputana, 602; Madras, 387; Mysore, 435; Hyderabad, 361; Bengal, 358; Central India, 135; Burma, 51; and Kashmir, 2.

*The Punjab Jails.*

In reviewing the Jail Administration Report for last year the Lieutenant-Governor fully agrees with the Inspector-General that the question of combating tuberculous disease is one of pressing necessity. To some extent the ravages of tubercle in jails are merely a reflection of the hold that it is getting on the population outside the prison walls. Still, there is some ground for thinking that there is something in jail life that predisposes to the disease. Sir Louis Dane desires to be informed whether the Inspector-General would advise a detailed inquiry by a pathological expert as to the etiology of tuberculous disease in the Punjab jails. As regards the treatment of youthful offenders, his honour suggests that the more frequent use of the provisions of Section 562, Criminal Procedure Code, or the infliction of petty fines would do much to remedy the evil. As regards whipping as a punishment for jail offences, his honour does not consider it possible to lay down a hard and fast rule. Whipping, he thinks, may be more necessary in certain states of discipline and in cases of certain individuals than in others.

*Phthisis in India.*

The following letter from the Government of India has been circulated to all local governments and administrations: "The attention of the Government of India has been drawn to the prevalence of tuberculosis diseases in India and to the great increase of phthisis in recent years in larger towns and cities, and it has been represented to them as most desirable that well-equipped sanatoria should be established with as little delay as possible in different parts of India for the treatment of tuberculosis patients. The Government of India are advised that the treatment of phthisis in the early stages of the disease in sanatoria in which patients can receive the most minute daily attention of specially experienced physicians, affords the only hope of cure, and they believe that many valuable lives will be saved if suitable institutions for treatment of tuberculosis patients are established in this country. The Government of India desire to commend this question to your earnest consideration, and will be glad to be informed in due course what action you propose to take or consider practicable. They think that funds for the purpose of establishing sanatoria will probably be found by private beneficence, and it is suggested that the coöperation of the charitable public may be invited."

*Tuberculous Disease in Ceylon.*

The commission appointed to inquire into the conditions of tuberculous disease in Ceylon has recommended the introduction of the system of compulsory notification of cases, the segregation of sick from the healthy, the establishment of a dispensary for out-door treatment in large centres where the disease is prevalent, the establishment of sanatoriums and of hospitals for advanced cases, and the education of the people in the prevention of phthisis. The commission is also of opinion that an anti-tuberculosis society should be established in Ceylon with branches in every important centre, and facilities should be provided for the free examination of sputum and other material for the bacillus of tubercle.

*The Madras Memorial to King Edward VII.*

The Government of Madras has issued its orders on the scheme proposed by the committee appointed in connexion with the subscriptions raised under the King Edward VII. Memorial Fund. The scheme of the committee was for a special consumptive hospital about ten miles out of Madras, but this has been rejected on financial grounds. The committee also suggested the provision of three sanatoriums, but here, too, the Government has deemed it advisable to limit the scheme. One sanatorium is proposed to be established at Coimbatore. A contribution will be given to the Missionary Sanatorium at Madanapalla. The sanatorium to be established at Coimbatore will be of 50 beds, and not 200 as originally proposed. The Government considers the entire funds should be devoted to this. The committee also suggested the provision of one phthisis ward at each district headquarters hospital. The Government proposes that a phthisis ward should be provided at a few selected hospitals at the cost of local funds aided by a grant from the Government. The Bangalore Civil and Military Station Committee has introduced very stringent by-laws for the licensing of all dogs. These are the most stringent rules yet in force in India against rabies.

*The Asiatic Society.*

The medical section of the Asiatic Society had recently a discussion on Hepatitis and Hepatic Abscess. Lieutenant-Colonel H. W. Pilgrim, I.M.S., read a most interesting paper. General support was given to the ipecacuanha treatment reintroduced by Major L. Rogers, I.M.S. A long but interesting paper on Epidemic Dropsy was read by Dr. H. N. Ghose at the Calcutta Medical Club.

*The Bombay Medical and Physical Society.*

At the annual meeting of the Bombay Medical and Physical Society the new committee was elected, with Dr. N. F. Surveyor as secretary. Dr. S. A. Powell showed a heart, the left ventricle of which was ruptured by a blow of the fist. With the exception of a small patch of atheroma in the transverse portion of the aorta, the body was otherwise healthy. Dr. L. G. Gate showed a curious case of syphilitic affection of the humerus.

*New General Hospital, Lahore.*

The chief topic of medical interest is the new General Hospital to be built in connexion with the very liberal subscriptions gathered to commemorate the love for the late King Edward VII. There are two sites for the same at present being considered. One of them, which is the one most likely to benefit the locality of the present hospital, will open up an existing insanitary site. The Punjab will thus come to the fore in the matter of a first-class up-to-date hospital like other presidencies. The new health officer is busy with the local difficulties *re* sanitation. A proposal has been put forward for the creation of a Punjab medical society, and seeing that there are a large number of practitioners and plenty of material, the outlook for this is promising. Besides, it will bring together the various members of the fraternity.

*United Provinces Exhibition.*

The all-absorbing topic at Allahabad is the United Provinces Exhibition. Probably no exhibition in India has been worked out on so large a scale and in so business-like a manner. The hygiene section is full of interest.

*Sanitary Matters at Simla.*

Sanitary matters are the only medical features to note at present. The special journal named *Paludism*, edited by Major

S. P. James, I.M.S., has now been issued in connexion with the recommendations of the Simla Conference on Malaria. The special class at Amritsar for malaria investigations has just closed its second course. The Pasteur Institute at Kasauli continues to do good work, while too much praise cannot be given to the keen work carried out by Lieutenant-Colonel David Semple, R.A.M.C. Colonel R. H. Firth, R.A.M.C., Army Headquarters, has issued a special paper to all his officers on the examination of drinking water.

*General.*

The chief general medical subject of interest over the greater part of India is, at this season, the plague. Its seasonal rise has already been most pronounced in some presidencies. With an early winter, and possibly a severe one, it is more than possible the plague will be felt with some severity in certain localities. Anything about plague is of interest to India. We now have the views of two young plague advisers, and this has in one province been connected with a special committee chiefly of non-medical gentlemen. General rat trapping has been condemned. The details of the report have already been made public. No doubt each of us has his own ideas, but it seems strange that with a disease which is affecting all presidencies the general lines to fight it should not be the same throughout the country. If anything is done in any one province it should surely be subjected to a special committee of experts before it is permitted to be adopted. What is wanted is a *uniform* fight against the disease throughout the country rather than changes introduced by the varying views of men who, from the exigencies of the service, happen to be in charge temporarily. I may be wrong, but it seems to me that if rat destruction is to be condemned as a measure of importance in the Punjab it is also time it was abolished in other provinces. But, in the interest of the public, before such measures are abolished it would be as well to have the verdict of a body of men who should be permanently established until plague ceases, and whose verdict should be final.

Dec. 28th, 1910.

## NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

*The Soya Bean.*

WITHIN the past three years the outstanding merits of this pulse have come prominently to the front, and its export from Manchuria, where most of it is raised, has lately assumed very large dimensions. For the past 2000 years it has been used in North China for making bean curd, a thick nutritious jelly eaten daily by all classes of the people. A widely used vegetable oil is also expressed from it, the refuse left over serving for cattle food and manure for sugar plantations. Recent analyses have proved its nutrient superiority to all cereals. This bean, a product of the *Soja hispida*, a species belonging to the papilionaceæ, is indigenous to China, but it can be grown in Europe; there are reports of its successful culture in Russia, Germany, and France. It is easy to rear, does not demand special skill on the part of the farmer, and does not require specially favourable soil or climate. It is a cheap product, each bean when sown multiplying itself, on an average, 450 times. On account of its great nutrient value it is well worth medical attention, more particularly in diabetic cases, because of its comparatively small proportion of starch. *Composition.*—Dividing its constituents into four main groups: 1. The albumin forms about 40 per cent. of the bean. 2. Fats average 20 per cent. 3. Carbohydrates: The beans contain sugar to the amount of 8 to 11 per cent. It is a disaccharose, $C_2H_{22}O_{11}$, and closely resembles cane sugar. Starch (all soluble) never exceeds 10 per cent., which is much lower than wheat and other grains, where the proportion is about 70 per cent. 4. The mineral matter is high, varying from 4 to 6 per cent. Phosphorus, sulphur, sodium, potassium, calcium, and magnesium are present. The most abundant salt is sodium phosphate. Advocates of the fleshless diet have to contend with the large amount of indigestible cellulose which occurs in vegetarianism. This cellulose is present in 4 to 11 per cent. of the soya bean, but is very easily eliminated from the other products. Bean curd is entirely free from it. China is not a milk-drinking country, notwithstanding the high prevalence of tuberculosis which I have noted in previous letters. To replace the lack of milk the dried bean is ground up and mixed with water. The resultant emulsion makes a most excellent vegetable milk which resembles animal milk in that it coagulates. Wheat and other beans emulsified in the same way, if heated gently and acidified, will not coagulate as cow and bean milk do. Comparing this bean with wheat, it will be seen that it is richer than wheat in everything but starch. It contains nearly three times as much albumin, 15 times as much fat, and between two or three times as much mineral matter. For making biscuits, soup powder, infant and other foods, the soya bean will be widely used in future when its dietetic value becomes better known. It also forms a good basis for making candles and soap. Soya vinegar is the main constituent of several well-known piquant sauces. I append some comparative figures, the work of a French-trained Chinese chemist, Mr. Li Yu Ying, from which it can be noted how favourably this bean compares with other foods in common use. *Minerals.*—Soya bean, 4·4 per cent.; rice, 1·2 per cent.; eggs and meats, 1 to 1·5 per cent. *Starch.*—Rice, 74·4 per cent.; wheat, 66·70 per cent.; flat beans, 57·6 per cent.; soya bean, 11·06 per cent. *Amount of various foodstuffs equivalent to 100 grammes of gelatin.*—Soya bean, 264; bean curd, 475; flat bean, 812; unboiled rice, 1176; bread, 1205; boiled rice, 3616; vegetables, 7142; potatoes, 7790. I understand this bean was introduced into England over a hundred years ago, but no attempt was made to cultivate it. English firms are now entering the field and taking a large part in the exportation of the bean from Manchuria. This increasing demand is shown in the customs returns. Thus, whereas the export last year was 200,000 tons, it is almost 500,000 tons this year.

*Plague in Manchuria.*

A virulent epidemic has broken out at Tsitsihar and the neighbourhood of Harbin on the Russo-Manchurian frontier. The daily returns of deaths have been from 500 to 600, and the majority of cases are reported as being pneumonic plague. This outbreak is an instance of the persistence of B. pestis under extremes of temperature. It is probably no exaggeration to say that North-Western Manchuria is one of the coldest parts of the world. 49° below zero (81° of frost F.) have been recorded in winter, and, at the present time of the year, when a north wind blows, life is almost unbearable in the open for more than short periods of time. It is too cold for snow unless heavy falls occur at the very beginning of winter. There is perpetual sunshine and the cold is very dry. Under such climatic conditions the inhabitants and animals keep indoors as much as possible and infection is easily spread, especially when the plague is of the pneumonic variety. The Russian authorities, at the request of the Siberian Railway Administration, have been active in sending troops and doctors, and have established a picket line of Cossacks on the Manchurian frontier to guard against the further ingress of Chinese coolies, who, in order to evade the rigorous medical inspection at Pogranichnaya railway station, leave the train on the Chinese side of the frontier and cross the boundary on foot. A cordon has also been drawn round the plague-infected area and only Europeans and a few known Chinese are allowed to cross. These vigorous measures have aroused some resentment among the Chinese, who in some instances, no doubt due to difference of language, customs, and habits, were roughly handled. The Chinese prefect at Harbin received official orders from Peking to organise plague preventive measures and to establish isolation hospitals and medical inspection bureaux. To help him in this work the Government has sent Dr. Mesny, a French medical man with previous plague experience, and Mr. Gnoh Lean Tuck, M.D. Camb. Dr. Tuck had a fine medical career in England, where he held research scholarships in pathology and bacteriology, afterwards studying at the Hygienic Institute, Halle, and the Pasteur Institute, Paris. These two medical men have been given a free hand by the Imperial Government and are to coöperate with the Russian authorities to bring every preventive measure possible into effect. This is noteworthy as being the first occasion in which the Government has shown itself alive to the dangers of allowing the unchecked spread of an epidemic outbreak.

The Russian Government has put its plague measures in the hands of Dr. Zabolotnui, a noted bacteriologist who made a reputation for himself in plague investigation in Odessa some time ago. He has been given a staff of 15 doctors to assist him. The latest news to hand is that the epidemic is showing a diminution in Manchuria, where the mortality is less than during the previous week, but there are still a good many cases and deaths in Harbin, sufficient to cause anxiety. I am unable to give official rates, as no figures have as yet been published, though it is said the deaths have hitherto numbered some hundreds per week.

Peking, Dec. 24th, 1910.

# Medical News.

## EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF ENGLAND.

At the Second Professional Examination in Anatomy and Physiology, held on Jan. 5th, 6th, 9th, and 10th, for which 81 candidates presented themselves, of whom 51 were approved and 30 were rejected, the following gentlemen were successful:—

Ahmed Abdelal and Francis Dighton Annesley, Guy's Hospital; Edgar Bernard Argles, St. Mary's Hospital; George Aspinall-Stivala, St. Bartholomew's Hospital; Henry Cecil Billings, London Hospital; Harold James Bower, B.A. Cantab., Cambridge University; Charles Frank Burton, London Hospital; John Stanley Cocks, Guy's Hospital; Louis David Cohen, London Hospital; George Malcolm Coope, Manchester University; Denis Clarence Cooray, L.M.S. Ceylon, Ceylon Medical College; Eric David Despard Davies, Cambridge University; Robert Ellis, Birmingham University; Edward Dance Fountain, St. Mary's Hospital; Vraspillai Gabriel, L.M.S. Ceylon, Ceylon Medical College; Alexander Percival Green, London Hospital; Harold Stanley Groves, Guy's Hospital; Howell Gwynne-Jones, London Hospital; Mohammad Zaky Hanafy and Arthur Martin Henry, L.D.S. Eng., Guy's Hospital; John Higgins, St. Mary's Hospital; Thomas Henry Jackson, Charing Cross Hospital; John Wallace Kemp, Guy's Hospital; Harold Dunmore Lane and David Lewis, London Hospital; Joseph Lloyd, Westminster Hospital and King's College; Donald Henry McDonald and Douglas Duncan Malpas, Middlesex Hospital; Percy Uvedale Mawer, St. Bartholomew's Hospital; James Denis Mercer, Manchester University; Harold Parker, Leeds University; Mahamarrakkelegey Gregory Perera, Ceylon Medical College and University College; Michael Gladstone Pettigrew, Sheffield University; Alfred Cleveland Pickett, B.A. Cantab., Cambridge University and St. Thomas's Hospital; William Reginald Pryn, Guy's Hospital; Herbert Jack Rawson, St. Thomas's Hospital; Philip Hugh Rawson, London Hospital; Edward Ebenezer Samaraweera, Ceylon Medical College and King's College; Charles Pearse Crodacott Sargent, St. Bartholomew's Hospital; Abdel Khalek Selim, Guy's Hospital; Jagannath Vishnu Shirgaokar, L.M.S. Bombay, Bombay University and Middlesex Hospital; Charles Rees Smith and Frederick Lionel Spalding, Guy's Hospital; William Allan Stewart, London Hospital; Evelyn Alexander Sutton, Charing Cross Hospital; Thomas Harold Thomas, Arthur Roland Turtle, and James Anderson Watson, London Hospital; John Delafosse Wilkinson and Sydney Arthur Wilkinson, St. Thomas's Hospital; and Leslie Douglas Wright, Guy's Hospital.

At the quarterly examination in Practical Pharmacy, held on Jan. 12th, the following candidates were approved:—

Ralph Cay Briscoe, Oxford University and St. George's Hospital; Ronald Edgar Russell Burn, St. Bartholomew's Hospital; Maurice Burnett, King's College and St. George's Hospital; Percy Herbert Burton, London Hospital; Allan Stanley Coalbank, St. Bartholomew's Hospital; Joseph Coplans, St. George's Hospital; John Hamilton Cumming, Cambridge University and St. Bartholomew's Hospital; William Dale, St. George's Hospital; George Arthur Ewart, B.A. Cantab., Cambridge University and St. George's Hospital; Samuel Amery Faulkner, Manchester University; Bernard Grellier, L.D.S. Eng., Charing Cross Hospital; Harold Kinder Griffith, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; John Cecil Hallinan and Walter Parker Harrison, L.D.S. Eng., Charing Cross Hospital; George Ashby Hooton, St. Bartholomew's Hospital; Edward Eastaugh Johnson, private study; Frank Winter Lawson, Guy's Hospital; Vernon Edmund Lloyd and Reginald Hutchinson Lucas, Guy's Hospital; George Oliver Maw, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Harry Millett, Guy's Hospital; George Nelson, Charing Cross Hospital; Lily Fanny Pain (Miss), Royal Free Hospital; John Lansdowne Perceval, Harry Platts, and Courtenay Henry Gerard Pochin, Guy's Hospital; Frank Aubrey Powell, B.A. Cantab., Cambridge University and London Hospital; Peter Warwick Ransom, Cambridge University and St. Bartholomew's Hospital; Edward Gordon Reeve, Guy's Hospital; Thomas Conrad Reeves, London Hospital; George Andrew Russell, Birmingham University; David Scott, London Hospital; Alan Ker Soutar, B.A. Cantab., Cambridge University and St. Mary's Hospital; Robert Cyril Wilmer Staley, Guy's Hospital; Elliott John Storer, St. Bartholomew's Hospital; Oscar Ramsay Unger, University College Hospital; Bernard Thomas Verver and Walter Palmer Vicary, Guy's Hospital; Ernest White, L.D.S. Eng., Sheffield University and Guy's Hospital; and Arthur Tudor Williams, London Hospital.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At the Preliminary Science Examination for the Licence in Dental Surgery of the Royal College of Surgeons of England the following gentlemen were approved in the subjects specified below:—

*Chemistry and Physics.*—Ronald William Anderson-Jardine, Middlesex Hospital; Reginald Willis Ballard, Guy's Hospital; Henry Claude Carter, Middlesex Hospital; James Douglas Crawford, Liverpool University; George Lambert Cutts, Herbert James Edwards, B.A. Wales, and Arthur Gerald Forrest, Guy's Hospital; Reginald John Inder, Northern Polytechnic Institute; Howell James, Plymouth Technical School; Sydney Emil Johnson, Tonbridge School; Oswald Nelson Mash, Guy's Hospital; Glenn Fowler Musson, Leeds Institute of Science and Art; Reginald Harry Rix, Norwich Technical Institute; Stanley Stevens, City of London College; and Eric Edgar Wookey, Bristol University.

*Chemistry.*—Kevern Batten, Bristol University; Walter Alexander Crane, Liverpool University; Arthur Thomas Dally, Charing Cross Hospital; Joseph James Luckett Hollington, Brighton Technical College; Eustace Fernando Llarena, Guy's Hospital; Wallis John Milton, Bristol University; Frank Edwin Rudd, Norwich Technical Institute; and Harold Vincent Wolfenden, Halifax Technical School.

*Physics.*—Leslie Alabone, Brighton Municipal Technical College; Ernest Archibald Dawson, West Ham Technical Institute; Reginald Fox, Liverpool Technical School; and Eric Carson Nicholls, Guy's Hospital.

At a quarterly meeting held on Jan. 12th the following diplomas were conferred upon the undermentioned gentlemen, who have now complied with the respective by-laws:—

*Diploma of Fellow.*—Walter Burford Johnson, M.B., B.S. Lond., M.R.C.S., L.R.C.P., St. Thomas's Hospital.

*M.R.C.S.*—David Scurlock, St. Mary's Hospital.

*L.D.S.*—Gerald John Harborow and Linthall Harry Leatherby, Charing Cross and Royal Dental Hospitals.

## FOREIGN UNIVERSITY INTELLIGENCE.

*Amsterdam:* Dr. C. T. Van Valkenburg has been recognised as *privat-docent* of the Anatomy of the Nervous System.—*Bologna:* Dr. Alessandro Codivilla has been appointed Extraordinary Professor of Orthopædic Surgery.—*Brussels:* A School of Tropical Medicine has been established. The Belgian Ophthalmological Society has elected the following as Honorary Foreign Members: Dr. Angelucci of Naples, Dr. Axenfeld of Freiburg, Dr. Hess of Würzburg, Mr. W. H. H. Jessop of London, Dr. Landolt of Paris, and Dr. Straub of Amsterdam.—*Erlangen:* Dr. L. Hauck, *privat-docent* of dermatology, Dr. E. Kreuter, *privat-docent* of surgery, and Dr. Weichardt, *privat-docent* of experimental therapeutics, have been granted the title of Extraordinary Professor.—*Freiburg:* Dr. Bacmeister has been recognised as *privat-docent* of Medicine.—*Gratz:* Dr. Erich Baumgarten and Dr. Eduard Urbantschitsch have been recognised as *privat-docenten* of Odontology.—*Halle:* Dr. Bencke of Marburg has been appointed Professor of Pathological Anatomy in succession to Dr. Eberth, who is retiring.—*Jena:* Dr. Kionka, director of the Pharmacological Institute, has been granted the title of Honorary Professor.—*Kieff:* Dr. W. Dobromysloff of Tomsk has been appointed Professor of Operative Medicine and Topographic Anatomy.—*Marburg:* Dr. P. Esch of Greifswald has been recognised as *privat-docent* of Gynæcology.—*Munich:* Dr. R. Hecker and Dr. J. Trumpp, *privat-docenten* of Pædiatry, Dr. Baisch, *privat-docent* of Gynæcology, Dr. Seeman, *privat-docent* of Physiology, and Dr. Notthaft, *privat-docent* of Urology, have been granted the title of Extraordinary Professor.—*New York (Polyclinic Medical School and Hospital):* Dr. David Edward Hoag has been appointed Lecturer on Neurology and Psychiatry.—*Palermo:* Dr. A. Dionisi of Modena has been appointed to the chair of Pathological Anatomy.—*Pavia:* Dr. Carlo Bezzola and Dr. Luigi Preti have been recognised as *privat-docenten* of Internal Pathology.—*Philadelphia (Medico-Chirurgical College):* Dr. Horatio C. Wood, jun., has been appointed to the chair of Materia Medica and Therapeutics in succession to the late Dr. Shoemaker.—*Philadelphia (University of Pennsylvania):* Dr. Allan Smith has been appointed to the chair of Tropical Diseases.—*Pisa:* Dr. Arbace Pieri has been recognised as *privat-docent* of Internal Pathology, and Dr. Filippo Neri as *privat docent* of Hygiene and State Medicine.—*Prague (German University):* Dr. J. Gad, Professor of Physiology, is retiring at the close of the present winter session.—*Rome:* Dr. Guido Senni has been recognised as *privat-docent* of Experimental Pathology, and Dr. Vincenzo Nicoletti as *privat-docent* of Orthopædic Surgery.—*Rostock:* Dr. Gerhard Hosemann has been

recognised as *privat-docent* of Surgery.—*San Francisco (University of California):* Dr. H. B. Graham has been appointed Adjunct Professor of Hygiene.—*Saratoff:* Dr. B. Slofftsoff of the Military Medical Academy, St. Petersburg, has been appointed to the chair of Pharmacology and Toxicology.—*Sienna:* Dr. Cesare Biondi of Cagliari has been appointed to the chair of Forensic Medicine in succession to Dr. Mirto.—*Strasburg:* Dr. Paul Uhlenhuth, Director of the Government Bacteriological Department, has been appointed to the Chair of Hygiene in succession to the late Professor J. Forster. Dr. Gildemeister, *privat-docent* of Physiology, Dr. Schlesinger, *privat-docent* of Children's Diseases, and Dr. Fuchs, *privat-docent* of Anatomy, have been granted the title of Professor. Dr. Vogt, Oberarzt of the Children's Clinic, has been recognised as *privat-docent* of Pædiatry.—*Tübingen:* Dr. Gottlieb Olpp has been recognised as *privat-docent* of Tropical Diseases.—*Vienna:* The Austrian Cancer Campaign Society has elected as Honorary Foreign Members Dr. Bashford of London, Dr. Borrel of Paris, Dr. Czerny of Heidelberg, Dr. Ehrlich of Frankfort, Dr. Jensen of Copenhagen, Dr. Orth of Berlin, and Dr. Winter of Königsberg.—*Würzburg:* Dr. H. Kelly has been recognised as *privat-docent* of Pathological Anatomy.—*Zürich:* Dr. Schuhmacher has been recognised as *privat-docent* of Surgery.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the above society was held on Jan. 11th, at 11, Chandos-street, Cavendish-square, Dr. G. F. Blandford, the President, being in the chair. Eight directors were present. Five medical men were elected members of the society. Since the last court one of the vice-presidents, Dr. James E. Pollock, had died. Dr. Pollock was one of the oldest members of the society, being elected a member in 1866. The sum of £1281 was voted for the payment of the half-yearly grants to the widows and orphans who are on the books of the society. A legacy of £200, free of duty, was received from the executors of the late Miss Emma H. Peregrine. The invested funds now amount to £100,900. Membership is open to any registered medical practitioner who at the time of his election is resident within a 20-mile radius from Charing Cross; the subscription is 2 guineas per annum. Special terms are made for life membership, the sum payable being dependent on the age of the applicant. The next election will be on April 12th, and application forms for membership must reach the secretary on or before March 22nd. Any further information may be obtained from the Secretary at the offices of the Society, 11, Chandos-street, Cavendish-square, London, W.

AN APPEAL FOR NEW LABORATORIES FOR UNIVERSITY COLLEGE.—In 1909 an appeal was made by a committee of University College, with the approval of the Senate of the University of London, for the sum of £70,000 for the erection of new chemical laboratories adjacent to the College. £25,000 of this amount were for the purchase of a selected site, the College having an option on it until Dec. 31st, 1910. Owing to the disturbing influences of the death of King Edward and a double General Election last year, the work of the appeal committee, of which Prince Arthur of Connaught is president, was seriously interfered with, and for this reason the option on the site has been extended to Jan. 31st. Of the £25,000 required only £14,000 have so far been secured, so that £11,000 remain to be collected. The present laboratories are entirely inadequate, and the importance of chemical research, both to the general advance of science and to commercial prosperity, is too obvious to need urging. Donations or promises may be sent to Prince Arthur of Connaught at University College, London, and must be prompt to be of any avail.

THE NEW LONDON DERMATOLOGICAL SOCIETY.—A new society has been formed for the study of diseases of the skin, the membership of which is open to any duly qualified medical practitioners. The inaugural meeting of the New London Dermatological Society was held on Jan. 16th at the offices of the British Medical Association, under the chairmanship of Dr. W. Knowsley Sibley. Dr. Phineas S. Abraham was unanimously elected the first president; Dr. William Griffith, honorary treasurer; and Dr. Norman Meachen (11, Devonshire-street, W.) and Dr. David Walsh (27, Welbeck-street, W.), honorary secretaries. In thanking those present for the honour conferred upon him, Dr. Abraham said that the new society would be supplemental or auxiliary to the Dermatological Section of the Royal Society of Medicine, its founders having no desire to be antagonistic to that body.

THE Queen has sent her annual subscription of £105 to King Edward's Hospital Fund for London.

NEWTON ABBOT (DEVON) WORKHOUSE INFIRMARY.—At the last meeting of the Newton Abbot board of guardians a provisional tender of £3074 was accepted for the erection of additional buildings for the workhouse infirmary.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. George Frederick Barker, formerly professor of physiological chemistry and toxicology in Yale.—Dr. John C. Munro, formerly lecturer in surgery in Harvard University.—Dr. Eustache, formerly professor of clinical midwifery in the University of Lille.—Dr. A. Smirnoff, professor of histology and embryology in the University of Tomsk.—Dr. Maximo Cienfuegos, professor of ophthalmology in the University of Santiago, Chile.—Dr. José Ortis y Herrara, formerly rector of the University of Cordova, and subsequently Governor of the Province. He died in Buenos Aires, aged 65 years.

AN INTERESTING CASE UNDER THE WORKMEN'S COMPENSATION ACT.—At Liskeard (Cornwall) on Jan. 11th, before his honour Judge Granger, a local farmer applied for the termination of an award under the above Act in respect to one of his labourers. The man had been injured through a horse of the farmer bolting and injuring his arm. The labourer had been awarded about 11*s.* weekly since April, but it was contended that the continuance of the disablement was entirely due to the respondent having neglected to work and use his arm, as ordered by the medical attendants. The respondent, however, contended that it was the injury which rendered him unable to follow his work. Medical evidence stated that the man had been urged to work his arm, and warned that if this was neglected he would never have the proper use of the limb; but the man refused to make any movements with the arm, although he gave no reason for his conduct. His honour said that "it was not everybody who could persist in giving themselves pain in order to arrive at what might not even be a definite end, it was more than could be expected," and he eventually dismissed the application.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—A council meeting of this association was held at the Holborn Restaurant on Jan. 13th, Dr. F. G. Crookshank being in the chair. The Order of the Local Government Board, 1910, relative to medical officers of health and sanitary inspectors, was discussed and the following resolution was unanimously carried:—

We welcome the measure of security of tenure to the Medical Officers of Health by the Order and recognise with satisfaction that the Board does not differentiate therein with respect to conditions of tenure between whole and part time medical officers of health, but regret the Board has not so far seen its way to assimilate the securing of tenure of medical officers of health to that enjoyed by Poor-law medical officers, and to make provision for superannuation in suitable cases.

The council also discussed the memorandum accompanying the Order, and it was resolved:—

That this council notes with extreme regret that the Local Government Board specially express an opinion that in the case of medical officers of health engaging in private practice, their private interests are apt to conflict with their public duties. For even if this opinion be correct it is obvious that any argument deducible therefrom applies with even greater force to medical officers of health who are entirely dependent upon their official salaries.

SCHOOL INSPECTION IN NEWPORT.—When the medical inspection of school children was first undertaken by the Newport education committee the medical officer of health, Dr. J. Howard-Jones, was appointed school medical officer, and an assistant medical officer was also appointed. The education committee has now decided that the medical department of the schools shall be separated from the health department of the town, and that Dr. Howard Jones shall no longer be school medical officer, but that his services shall still be available as expert adviser to the committee. Dr. H. R. Burpitt, who is now assistant medical officer, is to be appointed school medical

officer, and his duties are to include attendance at the school clinic which it is proposed to establish in Newport. The local medical practitioners consider that the work of the clinic should be in the hands of the Newport medical men and should not be undertaken by a whole-time official. In spite, however, of their protests, the course indicated has been adopted.

THE PLYMOUTH MEDICAL CHARITIES.—The late Mr. Henry Elliott Tracey-Elliott of Plymouth has bequeathed £3000 to the South Devon and East Cornwall Hospital, and £2000 each to the Plymouth Public Dispensary and the Royal Plymouth Eye Infirmary.

THE BRISTOL MEDICAL CHARITIES.—During 1910 the employees of Messrs. W. D. and H. O. Wills of Bristol voluntarily contributed £737 for the Bristol medical charities, and the workpeople of Messrs. J. and S. Fry collected £631 for the same cause.

## BOOKS, ETC., RECEIVED.

ALLENSON, R. H., LIMITED, Racquet-court, 114, Fleet-street, London, E.C.

Formation of Character. By Rev. J. B. S. Watson, M.A., Chaplain of H.M. Prison, Brixton, London. With Preface by Rev. G. P. Merrick, M.A., M.B., Formerly Chaplain-Inspector of H.M. Prisons. # Notes, Short Comments, and Answers to Correspondents.

## ENCEINTE.

*To the Editor of* THE LANCET.

SIR,—The note in THE LANCET of Dec. 31st, 1910, upon the etymology of the word "*enceinte*" does not say anything as to the date of its introduction into the vocabulary of the polite Briton as a substitute for the older and more medical "pregnant" or for the more purely English "with child." I infer, however, from its non-occurrence in a list of similar euphemisms before me that it was not in use in the opening years of the last century. The list referred to is appended to a letter addressed to the editor of an unnamed newspaper, which I find in a scrap-book once the property of an ancestress in the west country, who, if internal evidence suggests that she did not herself compile the "album," wrote her name in it in 1832. The letter is signed James English, and dated "Cornwall, Aug. 5, 1813," the name used being, no doubt, like the letter, an example of the author's humour. He writes:—

> "Having had occasion of visiting London this spring, a place I have not been in these forty years before, I took up my quarters, by her particular desire, at a female cousin's of mine who lives in the neighbourhood of Grosvenor-square—a lady who, though not many years younger than myself, moves and delights in the top of the fashion, as much as if she was only twenty-one. Having rested myself the first night after so long a journey, I began, as natural, to inquire after our friends and relations in town; when, happening to ask particularly after a young niece of mine, who had been married about nine months before, I was told, with an air of seeming indifference, 'that she was in *confinement*.' Alarmed at this news, I exclaimed, 'Good G—! what has she done to incur this disgrace?' 'Disgrace!' replied my cousin. 'What disgrace can there be in an *accouchement?*' Here I was as much at a puzzle as ever, till, upon a further explanation, I was told that my niece was *lying-in*, and that *confinement*, or *accouchement*, was the fashionable word to convey the meaning of my '*horribly country phraseology.*' 'Ho! Ho! cousin,' says I, 'if this be the case, it will be but civil in you to give me a list of those fashionable phrases, that I may not disgrace you or myself, whilst I stay in the metropolis.' After some pause and a look of silent contempt, which showed a superiority of understanding, she complied, and as the catalogue may be beneficial to other travellers as well as myself I enclose you a copy for your useful and entertaining Paper, and remain, Sir, your most obedient humble servant, JAMES ENGLISH."

The cousin in the neighbourhood of Grosvenor-square must have been a lively old lady to judge from a list from which two or three items may be cited as being perhaps of some historical interest to readers of THE LANCET:—

> Apothecaries = Doctors, chemists, or medical men.
> Man-midwife = Accoucheur.
> Pregnancy = In a family way; or to speak poetically in that way in which "women wish to be who love their lords."
> Cutting off a leg or an arm = Removing a limb.
> Suckling of children = Feeding of infants.
> Corncutters = Chiropodists.

The report of a trial pasted on another page of the same tattered volume is a reminder of the difficulty under which apothecaries used to seek to recover their fees, and certainly, in respect of the observations of counsel, of the change in forensic manners. "In the Common Pleas, during the trial of an action brought by Messrs. Price and Thompson, surgeons and apothecaries, for medicine and *attendance* afforded to a pork butcher named Gynn who had got a sore toe, Sir James Mansfield observed, 'I think it is a terrible thing that an apothecary cannot charge attendance unless he gives physic, whether it's wanted or not.' The daughter of the butcher, it appeared, had also a sore finger and an opening draught had been given her. 'See, gentlemen,' said Serjeant Shepherd, 'because this poor young lady happens to scratch her finger, she is condemned to an opening draught! Take care of your fingers, gentlemen, or the Lord have mercy on your bowels!'" The evidence in this case, given by an apothecary, who described himself as "of the old school," upon his own practice with regard to charges, was that he "never directly charged for attendance, but that when he thought it ought to be considered he said so in a *modest* manner at the foot of the bill." The same gentleman, by the way, showed that even in those days a scientific witness might sometimes get his own back from a cross-examiner who handled him roughly, for when in order to show that the opening draught was necessary treatment he was pressed to say that butchers lived well and were often of a gross habit of body, he retorted, "Yes, Sir, I think all professions live well when they can. No doubt, Sir, you take your wine." Serjeant Vaughan, counsel for the plaintiff, to whom this was addressed, laid stress upon the physical attributes of butchers in terms of refined humour which

make one try to recall the name of the gentleman supposed to be the prototype of his learned brother Buzfuz. He said to the jury in the course of his speech, "Oh, gentlemen, I would that I could produce their butcher here! No doubt he has a carcase bursting at every pore: and a toe that would take a quarter of a pound of meal to poultice it! *A toe!* I daresay it would cover Lord Wellington's position. Gentlemen, you all know what a butcher is! Many an opening draught it must have taken to open him and many a tonic to shut him up again!" In spite of his eloquence, however, Serjeant Vaughan consented to withdraw the record and to allow his client to be non-suited on Sir James Mansfield expressing the opinion that the charges were too high, and the reporter, in conclusion, informs us that the litigation was over a bill of two guineas, which the defendant had actually consented to pay, but only after legal proceedings had been commenced. As he would not pay the costs as well the case came into court with the above result, presumably at the ultimate expense of the unhappy surgeons and apothecaries.

The same scrap-book, it may be mentioned, contains a long account of a young lady named M'Evoy, of Liverpool, who had become blind and who after being blind-folded in addition was able to distinguish by means of her finger-tips the colours and shapes of objects, to read print, and to declare the nature of articles in an amazing manner, the peculiarity of her feats being that glass was placed between her and the objects to be named, not, be it observed, with a view to making her task more difficult by preventing her from feeling them, but because the interposition of the glass actually assisted her, and because she could not exercise the same perception without it. This was before the days of music-halls, and apparently Miss M'Evoy was a retiring young lady who did not perform for gain, and shunned publicity. Perhaps, however, she may have been a well-known character of whom authoritative records exist accounting for her performances.

By the way, I have omitted to point out that the note on "*enceinte*," to which I have referred above, begins by mentioning its pronunciation as a puzzle to many, but gives no rule with regard to it. May I suggest that *enceinte* is pronounced as if it were spelt "*en-sainte*," the second syllable being indistinguishable from the feminine of the French word for holy, and that it is not possible to print an exact English equivalent, the nearest, perhaps, being the name of a well-known artist, the "einte" having much the same sound as the "ant" in cant or pantaloon, pronounced with a slight Cockney twang.

I am, Sir, yours faithfully,

Jan. 7th, 1911. A. A.

## "606" ON TRIAL.

A PEKING correspondent sends us an extract from the *Peking Daily News* of Nov. 15th, 1910, stating that the Ehrlich-Hata 606 "will be ready to be supplied to the dispensaries and apothecaries in about four weeks time." It therefore calls on "the doctors and hospitals in China who intend to use this remedy quickly ..... to kindly send their orders at once to the nearest dispensary." "A native doctor," our correspondent writes, "who has no idea of antiseptics, &c., came to see me the other day, and told me he had ordered a quantity. When injected without attention to detail it will be interesting to see what mistakes occur." It is to be hoped that this "awakening of China" in respect of Occidental medicine will not be nipped in the bud by the chilling frosts of catastrophe.

## UNQUALIFIED DENTAL PRACTICE.

*To the Editor of* THE LANCET.

SIR,—I would like to appeal to our medical brethren who have much and well-deserved influence with, and opportunities to educate, their patients. When those patients may need our services, can they not be helped to discriminate between qualified and unqualified dentists? Dental affairs before the well-known House of Lords' pronouncement were sufficiently deplorable, but since that surprising decision matters have become truly appalling! The unqualified do not hesitate to shamelessly assert immense superiority over qualified dentists, while they dub their shops or offices "Dental Surgery," "Dental Institute," "Dental Rooms," &c., and the public in consequence may be deluded into assuming that this class are registered dentists. I am sure that if the members of the medical profession would courteously take the trouble to point out to their patients the importance of seeing that any practitioner employed is registered, we should have, at any rate, a somewhat improved condition of things dental.

I am, Sir, yours faithfully,

Jan. 2nd, 1911. REGISTERED DENTAL PRACTITIONER.

**COMMUNICATIONS not noticed in our present issue will receive attention in our next.**

## A DIARY OF CONGRESSES.

**THE following Congresses, Conferences, and Exhibitions are announced for 1911:—**

Feb. 20th–25th (Cairo).—Fifth International Congress for the Blind.
March 2nd–6th (Berlin).—Thirty-second Balneological Congress.
" 23rd (Paris).—First Congress of French Medical Journalists.
April (Berlin).—German Surgical Congress. (Thirty-ninth Annual Meeting.)
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
April 18th–20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.
" 19th–22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.
" 20th–22nd (Groningen).—Thirteenth Nature and Medical Congress.
May 30th (The Hague).—International Congress on Opium.
May (Washington).—Conference on the Protection of Industrial Property. (Question of False Marking of Goods.)
May–October (Dresden).—International Hygiene Exhibition.
May–October (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May–October (?) (London, Shepherd's Bush).—Coronation Exhibition.
June (Paris).—First Congress of the International Medical Association for the Prevention of War.
" (Los Angeles, Cal.).—American Medical Association.
June 5th–8th (Kolberg, Prussia).—Fifth International Congress of Thalassotherapy.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
July 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.
August 15th–21st (Dublin).—Royal Institute of Public Health.
" 30th–Sept. 6th (Portsmouth).—British Association.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September (Brussels).—Exhibition of Fractures.
" (Turin).—International Congress of Pathology.
" (Genoa).—International Exhibition of Marine Hygiene.
Sept. 11th–15th (Berlin).—National Congress for the Study and Prevention of Infantile Mortality (*Gouttes de Lait*).
" 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
" 18th–23rd (Sydney).—Australasian Medical Congress.
" 18th–24th (Turin).—Fourth National Congress of Hygiene.
" 24th–30th (Rome).—International Congress on Tuberculosis.
" 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.
October (Cologne).—International Congress of Criminal Anthropology.
Oct. 1st–4th (Liége).—Second Congress of Alimentation.
Dec. 4th–9th (Havana, Cuba).—American Public Health Association.
(Date not fixed) (Montreal).—Canadian Medical Association.
(Date not fixed) (Rome).—International Exhibition of Social Hygiene.
(Date uncertain) (Turin).—International Exhibition of Industry and Labour.

**In 1912:—**

Spring (London).—Second Optical Convention.
July (?) (Cologne).—International Congress of Nurses.
September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
" Visit of German Medical Men to America.
Nov. 22nd–29th (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.

**In 1913:—**

(London).—Seventeenth International Congress of Medicine.
(London).—Historical Medical Exhibition. (Organised by Mr. Henry S. Wellcome.)
(Dresden (?)).—International Conference on Cancer.
(Washington).—Congress of American Physicians and Surgeons.
August (Buffalo).—Fourth International Congress of School Hygiene.

**In 1914:—**

(Vienna).—Third International Congress for Professional Diseases.

**In 1915:—**

(London).—International Prison Congress.
(London).—Imperial Exhibition (?)

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1910 were given in THE LANCET of Dec. 31st, 1910.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1910 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 1 0 | One Year ... ... ... | £1 5 0 |
| Six Months ... ... ... | 0 12 6 | Six Months ... ... ... | 0 14 0 |
| Three Months ... ... | 0 6 6 | Three Months ... ... | 0 7 0 |

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

### TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

# An Address
ON
# THE HOSPITAL UNIT IN UNIVERSITY WORK.

*Delivered before the Northumberland and Durham Medical Society*

BY WILLIAM OSLER, M.D., F.R.S.,
REGIUS PROFESSOR OF MEDICINE, OXFORD.

GENTLEMEN,—I offer no apology for bringing before you an academic subject. Though the society has no direct university affiliation, as individual members you are interested in the development of the profession, and you take a pride in the rapid growth of the provincial universities, among which that of Durham, the northern sister of Oxford and Cambridge, takes precedence. What is university work? What is a hospital unit? What connexion have they with each other? And what interest have they for us, and for the community at large?

## THE FUNCTIONS OF A UNIVERSITY.

All are agreed that a university has a dual function—to learn and to advance learning. I use the word "learn" in the old sense—met with in the Bible and still used colloquially—as it expresses the mental attitude of the student towards his *alma mater*, "*totius litteratorii studii altrix prima.*" In mind, manners, and morals the young man seeks life's equipment when he says to his *alma mater* in the words of the Psalmist, "O learn me true understanding and knowledge." To learn the use of his mind, to learn good manners, and to learn to drive Plato's horses, form the marrow of an education within the reach of every citizen, but to which universities minister in a very special way; and it should be comprehensive, fitting a man in Milton's words "to perform all the offices, private and public, of peace or of war." The other great function of a university is to advance learning, to increase man's knowledge of man and of nature. Looking over the lecture list of any modern university one is impressed with the bewildering complexity of subjects taught, from Homer to Victor Hugo, from Tamil to internal secretions; but they may be roughly grouped into those dealing with man and those dealing with the cosmos about him. At any time these 800 years this division has been recognised, and though we have travelled a long way from the seven liberal arts which once comprised the whole range of study, it is not so much the nature of the subjects or their division that characterises modern education as a new spirit, a new attitude of mind towards them. No real progress was made until we returned to the Greek method—the pursuit of knowledge for its own sake. Out of the laboratories, as the result of work done by men absorbed in study and usually without the slightest bearing upon practical problems, came the three great revolutions of the nineteenth century—the annihilation of time, the substitution of the machine for the hand, and the conquest of disease. Physics, chemistry, and biology have given us control of the forces of nature. Faraday has harnessed Niagara, the power of which is now transmitted hundreds of miles away; the Curies have found the magic vril of Bulwer Lytton's "Coming Race"; and Pasteur has revealed one of the greatest secrets of life. It is characteristic of modern conditions that, hovering on the borders of the charmed circle of pure science, are those keen to turn every discovery to practical use. What good is knowledge unless it can be utilised in the service of man, asks a utilitarian age? The university of to-day, while ministering to the advancement of learning, is ready to teach how to make the learning profitable, so that everything in practical science, from household economy to aviation, finds its place. Schools specially adapted to special needs stand out as dominant features in the new programme, and Oxford and Cambridge, as well as Newcastle, Leeds, and Bristol, have felt the strong impulsion to develop the science which deals with human well-being. Of the old faculties which made up the *studium generale* medicine has been the one most profoundly affected by growth of modern science. What a revolution in our generation! Anatomy, physiology, and pathology, with their subdivisions of histology, embryology, physiological chemistry, and pharmacology, are now in laboratories controlled by specialists, whose ideals and work differ in no respect from those of their colleagues in the departments of physics, chemistry, and biology; and in many places large separate institutes are devoted to these subjects. The urgent need to-day is to extend this type of university work into our medical schools, so that *all* branches of the curriculum are included—medicine as well as pathology, surgery as well as anatomy, midwifery and gynæcology as well as chemistry. But here comes a difficulty—the practical schools which deal with these important subjects and their subdivisions are not under the control of the university, or at best have a very feeble affiliation. In this country the hospitals are either independent corporations, as here, or the medical school has evolved from the hospital, as in London, or there exists a mutual arrangement between the university and the hospital, as in Edinburgh. The difficulty is not insuperable—the same public-spirited citizens support both institutions; the hospital staff includes the teachers in the medical school. It only needs a rearrangement of responsibility, financial and educational.

## THE HOSPITAL UNIT.

What is a hospital unit, and how can it be brought into line with university work? First a word on what a hospital stands for in the community. Primarily for the cure of the sick and the relief of suffering; secondly, for the study of the problems of disease; and thirdly, for the training of men and of women to serve the public as doctors and nurses. A majority of hospitals deal only with the first of these objects, and incidentally with the third. All agree that a study of the problems of disease and the training of men and women in the technique of the art come within the sphere of the university. England has suffered sadly from an absence of great medical faculties, such as exist on the Continent; and nowhere is this more evident than in the dissociation of the hospital from the university. One consequence has been that the hospitals have been built by men who had no idea whatever of their scientific needs, and too often staffed by men who knew little and cared less for anything beyond their primary function. The present plan of hospital administration is a legacy from a period when university ideals had not reached the practical side of our medical schools. I need not do more than to refer to the arrangement of the staff which exists everywhere—three or four physicians, two or three surgeons, one or two gynæcologists, other specialists, and a group of juniors who serve as out-patient assistants, waiting for promotion to the wards. The pathological department, often only a dead-house so far as the hospital is concerned, is in no way coördinate with the others. Laboratories of bacteriology, clinical chemistry, microscopy, and of clinical physiology may or may not exist. This English system, which has spread to the United States and to the Dominions, has worked well in some ways, and is responsible for the general excellence of the hospitals, large and small. Go where you may, from the cottage hospital to the big city infirmary, the internal economy, so far as cleanliness, general care of the patients, and nursing, is admirable. Speaking from a comparatively wide experience of hospitals, I say unhesitatingly that the average level of comfort and care is nowhere so high as in this country, and in no small measure is this a tribute to the character and training of the women connected with them. But there are very glaring defects, foremost among which is the absence of proper laboratory accommodation in pathology, bacteriology, clinical chemistry, and microscopy. Time and again in large well-arranged hospitals I have asked for the pathological laboratory, and have been shown a dead-house; for the clinical laboratory, and have been told that it did not exist; and have been chagrined to find that even in so simple a matter as the determination of the nature of a tumour, or the bacteriological examination of a fluid, the institution had to depend upon the excellent clinical research laboratories of London. But an equally grave defect is in the internal organisation. The general hospitals, even those connected with medical schools, are as a rule overstaffed, four physicians or three, where there should be but one or two, and the same with the surgeons. On the other hand, in many the resident staff is miserably inadequate, and their time so taken up with routine that any scientific study of cases is impossible. A keenly interested physician has a capable house physician in good training—off he goes at the end of six months! and

the same weary process begins of putting a fresh man into harness. In the very best hospitals, with medical school affiliation, the arrangements are on old and very unsatisfactory lines. In long, uphill years the ambitious young man goes through the position of resident physician, medical registrar, assistant physician, and at 40 (if he is lucky!) gets wards. Then a visit two or three times in the week with a house physician, a certain amount of teaching, and possibly some laboratory work, but he has a living to get and practice becomes the first consideration. He has precious little pay, if any; there are no paid assistants; there is no continuity in the organisation; in fact, there is no organisation on modern lines. This can be changed if we can convince the authorities that the subjects of clinical work come directly within the sphere of the university, and that certain hospitals must be adapted to meet the demands of the scientific study of disease and the scientific training of students. The problem is how to place a dozen or more teachers in every medical school in the same relation with the university as the professors of physiology and of physics—how to give to each one of them a department organised on university lines, in which the three functions of a hospital may be utilised and coördinated. The hospital unit meets the condition—a department under the complete control of the university, or under the joint control of hospital and university. Take a medical faculty with, say, 300 students, for which the necessary hospital accommodation would be about 500–600 beds, a unit would represent a clinique in the continental sense, of which there would be five or six major, and as many minor—the former including medicine, surgery, midwifery and gynæcology, pyschiatry and neurology, pædiatrics, and ophthalmology; the latter, dermatology, dentistry, laryngology, otology, syphilis, and genito-urinary diseases. There might be, as at Berlin and Vienna, two or three medical and the same number of surgical units. In Vienna, for example, there are three completely equipped midwifery and gynæcological units, each with lecture rooms, laboratories, rooms for students, and the whole paraphernalia for teaching and research.

### THE ORGANISATION OF THE UNIT.

Let us take medicine, the one with which I am familiar. The components are the professor or director, 60 or more beds, an out-patient department, four or five laboratory rooms, and a staff. Let us deal with these in detail.

The *Professor* has three duties—to see that the patients are well treated, to investigate disease, and to teach students and nurses. He should be a man with wide sympathies and of trinocular vision. He should have a comprehensive and thoroughly scientific training, and should enter clinical medicine through one of three portals—physiology, chemistry, or bacteriology and pathology. He must be keenly practical, keenly scientific, fond of his patients, fond of his work, and devoted to his students. He should live as much in his wards and laboratories as do his colleagues in their laboratories of anatomy, physiology, chemistry, or physics. The question at once comes up, Is this possible? Can we expect surgeons, physicians, obstetricians, and specialists to devote themselves entirely to University work, and to carry out the three functions of the hospital, without regard to the public outside? Theoretically it sounds feasible, but in practice I do not believe it to be possible. In the case of a successful teacher with a widespread reputation, the public, to say nothing of the profession, could not be kept away from him. But it would not be unreasonable to ask such a man to devote at least one-half, or even more, of his time to the hospital duties. For the heads of the different units the university would go into the open market and seek the best men available. Under our present system the university choice of professors in the practical departments of the faculty of medicine is, as a rule, limited to men who hold hospital positions in a town. It is encouraging to see that the provincial universities are departing from this old practice, and I am very glad that you lost your distinguished townsman, Dr. George Murray, who was appointed to the chair of medicine in Manchester.

But it may be urged—have we not heard that the day of the pure clinician is over?—did not our *Opsonator maximus*, Sir Almroth Wright, pronounce his funeral oration a few months ago at the Royal Society of Medicine? Do not listen to him—*Clinicus perniciosus*, to quote Mindererus, with vision so myopic that he can see only applied bacteriology in clinical medicine. As is the twig, so is the tree, and with his upbringing such opinions are perhaps natural; and it is not for me to abuse an old friend, of whose good work no one has a higher appreciation. But in these days so winged are Sir Almroth Wright's words that they fly far and need a protest from one who has been keenly alive to every bacteriological advance in medicine. Think of what would have happened if a man of Sir William Broadbent's wide sympathies, clear judgment, and enthusiasm had had a great modern clinique at St. Mary's Hospital, such as those of Leyden or of Kraus at Berlin—do you suppose the bacteriological tail would have wagged the clinical dog? Far from it! Sir Almroth would have done just as good work as director of the bacteriological laboratory of the clinique, and vaccine therapy would not have received such tardy recognition, and would have been in just as satisfactory, or possibly in a more satisfactory position. A striking comment, too, on Sir Almroth's claims is the fact that the medical and surgical staff at St. Mary's are still on duty!

*Patients.*—In the case of the medical clinique the number will depend upon the size of the medical school. In a hospital to which many acute cases are admitted a male and a female ward with about 30 beds each, and with a few small extra rooms, would furnish ample clinical work for a senior class. There are continental cliniques in which double this number of patients are treated, and the matter is one for organisation. To make the teaching and the work of the unit effective, it is essential to give the professor control of an out-patient department, with proper arrangements for the study of the cases and for the teaching of the junior students. In how many out-patient departments is the university side of the hospital problem considered?

*Laboratories.*—It is a characteristic of modern medicine that every available science is pressed into her service in the study and treatment of disease. Any sort of rooms will do for laboratories. The very best of work has been done with the meanest sort of equipment. The ideal plan is that followed in certain hospitals, the new cliniques, for example, of the Cochin in Paris, in which each unit consists of two wards on either side of a central building, the lower floor of which is devoted to administration, and the upper to laboratory purposes. In every way it is a convenience to have the laboratory rooms in close proximity to the wards, and when feasible they should form an essential part of the unit, but for the sake of economy they may be merged, and all the pathological work concentrated in one building. Nowadays provision should be made for (1) cardio-respiratory physics and physiology: (2) bacteriology and vaccine therapy; (3) chemistry; (4) microscopy; (5) X ray and electrical work; and (6) a general laboratory for the students. From the standpoint of the teacher the most important of these is the large laboratory for the students, in which the subject of clinical microscopy is systematically taught to the juniors, each man having his own place and his own microscope, and in which the seniors work while acting as clinical clerks. No benefaction to the Johns Hopkins Hospital was more helpful to the medical school than that in which some kind friends gave the necessary money for a clinical laboratory. The best general clinical and pathological laboratory I have seen lately is that newly opened at the hospital which gave me my start in life, the Montreal General. The arrangements for students are admirable.

*The staff.*—The present arrangement existing in almost all English, American, and Dominion hospitals is antiquated, and in every way ill-adapted to modern conditions. A man is given a house physicianship for six months, or possibly a year; there is a senior resident physician, and there are laboratory assistants, who may or may not be at the disposal of the professor. Gradation, permanency, and specialisation should prevail as in any other university department. There should be four groups. First, the senior assistants nominated by the professor, holding university as well as hospital appointments, and who should be prepared to remain for an indefinite number of years. In a clinique of moderate size three such could be utilised. The first assistant, a man of some maturity, should be in full charge of the department in the absence of the professor. The position should be made attractive and ample opportunities should be given for original work and for teaching. From this group the professoriate throughout the country would be recruited. Secondly, the junior assistants, house physicians, appointed

annually and by competition from the members of the senior class. Thirdly, laboratory chiefs, who need not be resident; but it is a good plan to have one of the senior assistants in charge of the laboratories, and one who is at the same time responsible for the laboratory teaching of the students. The arrangements vary greatly at different cliniques in accordance with the leanings of the professor towards chemistry, physiology and physics, or bacteriology. Fourthly, an out-patient staff made up of assistant professors in the department, as a rule men in private practice, and who are in charge of the junior teaching. At the Johns Hopkins Hospital we had three men in charge of the medical out-patients, each of whom took two days in the week, each with his own staff of assistants and a group of students assigned as clinical clerks. Special out-patient departments may be managed by the clinique; for example, the Tuberculosis Dispensary, which at the Johns Hopkins Hospital, under the care of Dr. Hamman, has grown to be one of the most important departments of the hospital.

*Teaching.*—Entering one of the clinical units, a student should be made to feel a part of it, having his share in caring for the patients and in studying the disease, and even in the teaching. He should be made to feel that the hospital is his home. This has been one of the special boons enjoyed by the British medical student in his senior years; the hospital has been in reality the medical school, and there has not been that disassociation between the two which exists too frequently elsewhere. The teaching should be entirely practical. In a few systematic lectures some of the more rare affections may be considered. Brought into daily contact with disease, the students gradually learn to recognise it, and are taught the management of patients. In clinical lessons and in demonstrations the professor and the assistants would in the course of a year cover the ground very thoroughly. In amphitheatre cliniques it is easy to keep all senior students in touch with the department, while the special group, acting as clinical clerks, spend the greater part of their time in the wards. The five years of the curriculum should be divided equally, and the 30 months given to the hospital would enable a man to go the rounds of the departments and get a very full insight into the work. Hospitals have no vacations, and the old-time vacations should be done away with, and the school year divided into quarters, during which the work would proceed continuously. A man could take a week or so of vacation when he felt it was necessary, but it is high time a stop was put to an atrocious waste of time on the part of the students. The professor and his assistants should keep in mind the fact that the men entrusted to their care are to become practitioners, and as far as possible the practical work of the wards should be done by them. Upon one thing I would insist—that every assistant connected with the clinique taught. A few exceptional men, like the distinguished physicist, the late Professor Rowland, are really too good to teach; but for the majority, daily contact with students, and a little of the routine of teaching, keep us in touch with the common clay and are the best preservatives against that staleness so apt to come as a blight upon the pure researcher.

*Research work.*—Just as the big chemical laboratory of the university exists for research, so should the clinical units help to advance our knowledge of the causes of disease and of its treatment. The problems are innumerable, and in a well-organised clinique there will be men working at them in almost every department. A few of the better students may always be utilised for this purpose. The important thing is to keep one section at least of the clinique well in the fighting line, battling with the problems of to-day, in metabolism, immunity, cardio-respiratory physics, &c.

The other units would be organised in the same way, and, as I remarked, in large schools there could be three, or even four, medical and surgical cliniques. The important thing is to organise each unit on university lines. For example, the professor of psychiatry should be *ex-officio* in charge of the city asylum, managed as one of the departments of the university, and into which, as a matter of routine, each medical student would pass for one of his ten hospital trimestres.

The truth is, we need an active invasion of the hospitals by the universities. But—and here comes the rub—the universities must be willing to undertake their share of the expenses, and the men in charge of the units must be paid salaries sufficient to enable them to devote one half at least of their time to hospital work—to give it the first place in their lives. At present in many places, indeed one may say everywhere, the university does not pay enough for its hospital privileges. How much, I would like to know, does the University of Durham pay to the Royal Victoria Infirmary? Nowadays the physicians and surgeons give their time, but the public, through university channels, should pay this group of men, not only to care for their sick poor, but to train their doctors and nurses, and to study for them the problems of disease. It is impossible to separate the three primary functions of a large hospital, of the machinery of which the medical student is just as much a part as the nurse, and so involved are the new methods of diagnosis, of laboratory treatment, and of research with the utilisation of skilled scientific assistants that it would puzzle anyone to assign the proportion of cost to A, B, or C. A good rule is that followed at the Johns Hopkins Medical School—the University paid half of the salaries of those members of the staff who were directly engaged in teaching and one half, I think it was, of the laboratory expenses.

As the old order changes new developments must be met, and here in the provinces, less hampered by traditions and not tied in the chains of vested rights, you can reorganise the hospitals on these lines through the universities. I have not been discussing Utopia; it is being done elsewhere. In the United States and the Dominions these changes are rapidly progressing, and the hospitals, for example as in Toronto, are being built on a modern plan, with units such as I have described. It will take time and much money, but it can be done; in fact, it has to be done if British medicine is to adjust itself to the new conditions, and so maintain its splendid traditions. Nor is it a matter which concerns the mother country alone. In former days the over-seas students came here for all their work; now the majority of them take their qualifying studies at home and come abroad for post-graduate work. The students from various parts of the Empire should come to our universities and hospitals and find thoroughly organised departments, with laboratories as well equipped for the study of the problems of disease as are those of chemistry and of physics for the study of these subjects.

BY A. E. GARROD, M.D. OXON., F.R.C.P., F.R.S.,
PHYSICIAN, WITH CHARGE OF OUT-PATIENTS, TO ST. BARTHOLOMEW'S HOSPITAL, AND PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN.

THAT noises are produced in joints is a familiar fact, for such sounds are in some instances so loud as to be clearly audible to bystanders, and far more often attract the notice of the persons in whose joints they are produced. The loudest articular sounds are those which have little or no morbid significance, and, speaking generally, the most noisy joints are seldom those which are the seats of the more serious forms of disease. Apart from the more conspicuous reports and crackles above referred to, there are abnormal articular sounds, of much fainter character, which are only audible with the stethoscope, and, from experience gained from systematic examinations extending over some years, I have become convinced that auscultation affords valuable aid in the diagnosis of the several forms of morbid change to which the joints are liable.

The method of examination is very simple. The only apparatus needed is an ordinary binaural stethoscope, and any difficulty which may be experienced in keeping the mouth of the stethoscope accurately applied to the changing surface of a joint in movement is easily overcome by the use of a small chest-piece, or, better still, by affixing to the chest-piece one of the indiarubber ring coverings which are sold by instrument makers. A little practice enables one to dispense with any special chest-piece, and teaches how and where the instrument is best applied to the several articulations. Of all joints the knees are those which best lend themselves to such examination, and no difficulty is met with in keeping the chest-piece applied over the soft parts on either side of the patella. During the examination the joint should be slowly flexed and extended, either by the

[1] A paper read before the Medical Section of the Royal Society of Medicine on Jan. 24th, 1911.

patient himself or in a passive manner by the examiner. Auscultation of the shoulder-joint is also easy, and the sounds produced during rotatory movements, as well as during elevation and depression of the arm, may be alike studied. Nor is any serious difficulty met with in the application of the method to any of the larger joints, such as the elbow, wrist, or ankle. Even small articulations, such as the temporo-maxillary or the carpo-metacarpal joint of the thumb, admit of examination with the stethoscope.

I cannot pretend to give in this paper any complete or adequate account of the sounds heard in moving joints, nor of their diagnostic significance, for I can lay no claim to the knowledge required for the production of such an account. My aim is rather to direct attention to the value of this clinical method, and to stimulate others to employ it, in the hope that the accumulated experience of many observers may lead in time to a just appreciation of the meaning of the sounds and an accurate differentiation of their several varieties. Our knowledge of the meaning of sounds heard in auscultation of the chest has been built up by comparison of clinical observations with post-mortem findings, but the qualities of the sounds are in most instances indicative of the method of their production. Thus a pericardial friction sound strongly suggests its origin, and when we hear sibilus, the rush of air through narrowed passages is clearly indicated. Again from the time and distribution of a cardiac murmur the seat and nature of a valvular lesion may be inferred, and the inference drawn during life has been so often confirmed by examination after death that there is no longer any room for doubt as to interpretation, yet experience shows that even skilled observers sometimes are misled by clinical signs.

In the case of joints the opportunities of confirming our findings by actual examination of the parts are few, and therefore the acquisition of certain knowledge as to the meaning of articular sounds must be mainly a matter of clinical observation, checked by such information as X ray pictures afford—information which must, in the nature of things, chiefly relate to the condition of the bony structure. When examined with the stethoscope a normal joint of a young subject is silent. It is true that loud reports are sometimes produced in such joints, and can be produced by some persons at will. Such sounds have no morbid significance, and may be compared to the click produced by lifting a ball from a closely fitting socket; in other words, they are vacuum sounds.

In the joints of subjects past middle life abnormal sounds are often heard, even though the patient makes no complaint of his articulations, and is conscious neither of pain nor stiffness. They may be ascribed to the changes due to wear and tear, but experience teaches that in cases of incipient osteo-arthritis abnormal sounds may precede all subjective sensations. Thus when one knee is alone complained of, its fellow may exhibit well-marked auscultatory signs. On the other hand, silence of a joint is by no means a sure indication of health. In cases of synovitis, in which the articular surfaces are held apart by effused fluid, no sounds are heard, as a rule, but when the effusion has been absorbed a pronounced crackle becomes audible at any part to which the stethoscope can be applied, and this sound, to which the name of synovial crackle may be applied, is one of the commonest of morbid sounds heard in joints. Long after the attack of synovitis is past, especially in cases in which the joint which was its seat is apt to give trouble after any unusual use or strain, the synovial crackle may still be audible, and, as far as can be judged on clinical grounds alone, it would appear to indicate a swollen condition of the synovial membrane. In its most characteristic form it resembles closely the crackle heard when the stethoscope is applied to a region which is the seat of surgical emphysema.

It is not only when effusion is present that diseased joints are silent. A very limited experience of auscultation of tubercular joints leads me to believe that these are frequently or even usually silent, and the same is also true of joints affected by the more acute forms of rheumatoid arthritis, although in the later stages the synovial crackle is usually heard in them. This is in accord with the scanty post-mortem evidence available as to the condition of the joints in the acute stage of the disease in question, which tends to show that the joints themselves are at first but little implicated and that the inflammatory swelling is mainly periarticular. The knee-joints of patients in or past middle life, and especially of women about the period of the menopause, are often the seats of pain and stiffness, which is especially felt in kneeling, or in going up and down stairs, and for which medical advice is sought. In such joints a peculiar abnormal sound is heard, especially well when the stethoscope is applied on either side of the patella. In characteristic cases this is rather a scrunch than a crackle, and has a wholly different character from the synovial sound already described. The character of the scrunch suggests abrasion of cartilages rather than synovial swelling, and radiograms of the articulation in which it is heard usually show slight but distinct evidences of osteo-arthritic changes. I am strongly inclined to think that this scrunch is an early and important sign of osteo-arthritis. It must be mentioned, however, that cases occur in which it is difficult to decide to which class the sounds heard should be assigned, and it is more than probable that in many instances the synovial crackle and osteo-arthritic scrunch coexist.

It should be mentioned that I have here employed the words rheumatoid and osteo-arthritis to designate distinct morbid conditions, which I believe to be manifestations of two distinct diseases, and that I believe the osteo-arthritic scrunch to be a physical sign of that process which results in fibrillation and erosion of cartilages and the formation of chondrophytes and osteophytes.

There is another articular sound which is much less commonly heard than either of those which have already been referred to, and which can usually be felt as well as heard. It is a rubbing noise which suggests the friction of ill-lubricated surfaces upon each other, and is such as might result from the movement upon each other of eburnated surfaces of bone. However, such an explanation is not tenable in view of the fact that after persisting for a time the friction may wholly disappear, and it is in the more advanced stages of rheumatoid arthritis, rather than in association with osteo-arthritic changes, that this abnormal sound is heard. Into one or other of the above-mentioned categories the morbid sounds heard in joints appear to fall for the most part. Lastly, the friction which may be felt over inflamed tendon sheaths produces a quite characteristic noise, which must be distinguished from those produced within the articulations.

To sum up, it may be claimed for auscultation of joints that this method is capable of affording early warning of troubles in articular structures and sometimes reveals the commencement of disease in joints which to inspection and palpation appear to be normal, and which may even cause no discomfort to their possessor. Again, the method gives promise of help in the differentiation of articular diseases, and in distinguishing between those in which the cartilages and bones are implicated, and those in which the synovial membranes and soft parts around the joints alone suffer. If these claims be justified auscultation of joints does not merely supply information which can be equally well obtained in other ways, but promises to lead to the extension of our clinical knowledge of the conditions in which it is employed.

Chandos-street, W.

# TRANSPERITONEAL CYSTOTOMY FOR TUMOUR OF THE BLADDER,

WITH REPORT OF A CASE.[1]

BY SETON PRINGLE, M.B. DUB., F.R.C.S. IREL.,
SURGEON TO MERCER'S HOSPITAL, DUBLIN.

IT has long been recognised that the operative treatment of tumours of the urinary bladder is, to put it mildly, disappointing and unsatisfactory; indeed, such a well-known authority as Casper in his book on "Genito-Urinary Diseases" states that "patients do better and live longer without than with operation."

In considering this subject, we must remember that the vast majority of bladder tumours are epithelial in origin, that the majority of these are carcinomata, and that even the pathologically innocent tumours, the so-called benign papillomata, are often clinically malignant, inasmuch as they recur both *in situ* and as implantation tumours. We must

[1] Being a paper read before the Surgical Section of the Royal Academy of Medicine in Ireland on Nov. 18th, 1910.

also, however, remember that the bladder is poorly supplied with lymphatics, so that the growth of cancerous tumours is slow and that metastases are rarely formed.

At present the surgeon generally chooses the suprapubic route in attacking these tumours, as it is more satisfactory than the infrapubic, perineal, or vaginal route, and does not require the special skill and practice which enable a limited number of operators successfully to use the urethral route in selected cases. The suprapubic is, and probably will be, the operation of choice in dealing with tumours placed near the apex of the bladder; but, unfortunately, the great majority are situated at the base, and in dealing with these the disadvantages of this route are many and obvious. It is difficult to obtain a proper view of the growth. The hæmorrhage is difficult to control and further obscures the view. In the cases of malignant growths it is almost impossible to define their limits; and if the orifice of either ureter is involved, as it frequently is, the very greatest trouble is found in dealing satisfactorily with the severed ureter. There is also the danger of infecting the prevesical space.

The results also of the suprapubic operations have been most disappointing. Watson (1) has compiled statistics of the result of 662 suprapubic operations for tumour. He found that in 287 performed for benign papilloma there was an immediate mortality of 10 per cent. and a recurrence of 20 per cent. inside three years. In 375 performed for malignant growths the operative mortality was 27 per cent. and the rate of recurrence 63 per cent. inside three years.

The operation of intra- or trans-peritoneal cystotomy, to which I wish to call attention, obviates all the difficulties of technique which I have enumerated above. At the same time it lessens the immediate mortality, and will certainly improve our end-results as it enables us to deal much more radically with the growth. This operation was first performed by Harrington (2) for an intractable case of hæmorrhagic cystitis. He described the operative technique in detail, and is entitled to all the credit of proposing and carrying out an original procedure. As far as one can judge from a study of the literature, this operation was not again performed until March, 1907, when C. H. Mayo (3) employed the technique of Harrington in dealing with a cancer of the base of the bladder. Up to the present, as far as I have been able to ascertain from a fairly extensive study of the literature, some 21 cases of tumour attacked by this route have been reported. C. H. Mayo in 1908 published reports of 5 cases; and Judd (4) has since reported 10 further cases from the Mayo clinic. Of these 15 cases 9 were carcinomata and 6 benign papillomata. There was only one death, and that occurred in a man of 71, who had half his bladder removed for cancer, and who died from uræmia a week later; at the post-mortem examination his kidneys were found extensively diseased. Scudder and Davis (5) in 1908 published four cases, three of papillomata and one of benign papillary cystadenoma of the prostate. All these cases recovered. Primrose (6) and Cabot (7) in 1909 reported one case each of cancer successfully dealt with by this route.

On analysing these 21 cases we find that a large part of the bladder was resected several times, a ureter had to be transplanted at least on four occasions, and twice the prostate was also enucleated. In spite of these radical procedures the mortality was less than 5 per cent., which compares with a 10 per cent. mortality in the series of cases collected by Watson, in which the suprapubic route was used and the tumour only removed without any resection of the bladder wall. As regards the frequency of recurrence, it is yet too early to speak. Up to the time of publication of Judd's paper there had been three recurrences in Mayo's cases, on two of which he successfully re-operated. If we take these two operations and the case now reported, we find the operative mortality further reduced, as there was only one death in 24 operations—i.e., a mortality of 4·1 per cent.

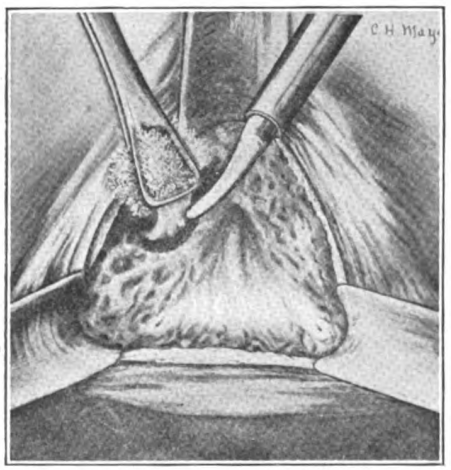
*Operation.*—After the bladder has been washed out and emptied the patient is placed in the Trendelenburg position. The peritoneum is opened by a long median incision extending for six inches or more up from the pubis. In malignant cases the interior of the abdomen is then carefully inspected, to eliminate the presence of metastases before proceeding further. If these are absent, as they usually are, or if the case is of a benign nature, the intestines are now carefully packed off with gauze. The superior peritoneally covered surface of the bladder is now seized with two forceps and a short median incision made into it. The interior is carefully swabbed out and the incision lengthened as much as necessary. In this way an excellent view is obtained. (Fig. 1.) If the tumour is pedunculated, it is grasped in forceps and removed with the knife or scissors, so that some of the normal mucous and submucous coats is also taken. The raw surface left should then be

FIG. 1.

Note the long abdominal incision well retracted, intestines protected by gauze, low posterior incision into bladder, internal meatus, ureteral orifices, tumour, and traction suture. (Scudder, *Annals of Surgery.*)

cauterised with the Pacquelin cautery, or, if preferred, the whole removal may be performed with the cautery. (Fig. 2.) Sutures will not, as a rule, be required, as the cautery controls the bleeding, and the raw surface may be left to granulate up. In malignant cases the whole thickness of the involved part of the bladder wall, whether covered by peritoneum or not, must be removed, the section being made

FIG. 2.



Cautery resection of papilloma of bladder. (Mayo, *Annals of Surgery.*)

through normal tissue. In some cases as much as half of the bladder wall has been removed, and in others the floor of the space left after removing the tumour has been formed by the fibres of the levator ani. If the ureter is involved in the growth, its orifice is removed *en masse* with the tumour, and it is divided above the involved portion. Its distal end is then re-implanted into the bladder, either through a separate puncture (Fig. 3) or through the original incision, and fixed there with catgut sutures. On completing the intravesical part of the operation the bladder wall is completely closed by a double row of sutures, an inner Connell suture of catgut

(Fig. 4), and an outer peritoneal suture of fine silk (Fig. 5).

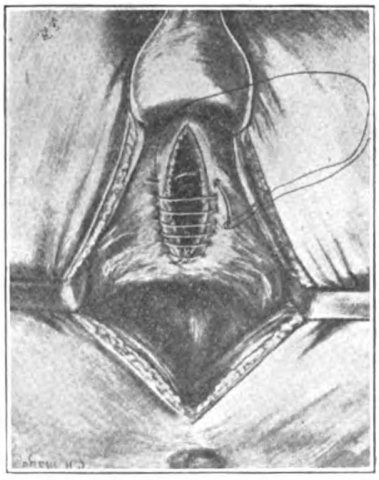
As a rule, the abdominal wound may be closed in its entirety, but if there has been any soiling of the peritoneum a drain may be left in for a few days. In a simple case it is not necessary to drain the bladder, as the patient generally passes urine voluntarily and at frequent intervals from the evening of the operation, and if there is any urethral spasm

FIG. 3.

Removal of large amount of bladder with transplantation of ureter. (Mayo, *Annals of Surgery.*)

a catheter can be frequently passed. Some operators, however, drain these simple cases by means of a catheter in the urethra. In severe cases, as for instance where the prostate has also been removed or a ureter transplanted, it is

FIG. 4.



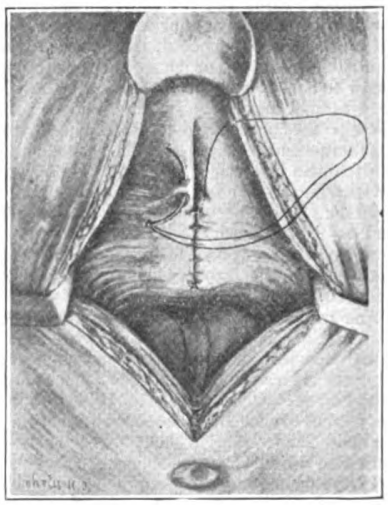
Showing method of closure of bladder incision. First row of sutures. (Mayo, *Annals of Surgery.*)

better to drain the bladder suprapubically through an independent incision into the bladder, made after the peritoneal cavity has been closed.

My thanks are due to the publishers of the *Annals of Surgery* for permission to use the accompanying illustrations.

*Report of case.*—The patient, a man aged 40, was sent to me by Dr. H. Powell of Nenagh. He complained of frequent attacks of painless hæmaturia during the past 12 months, each attack lasting several days. With the cystoscope I saw a large papilloma springing from the right side of the bladder, but it was impossible to clearly define its origin, as the floating papillæ, of which the bladder seemed to be full, constantly obscured the view. On June 1st I performed transperitoneal cystotomy as described. The tumour, which was of the size of a hen's egg, was pedunculated, the pedicle springing from the base of the bladder about an inch below and to the right of the right ureteral orifice, which was not interfered with. An excellent view was obtained, and the tumour was easily removed with scissors, a piece of normal mucous membrane being taken with it. The raw area left, which was about an inch square, was then cauterised with a Pacquelin cautery, and one stitch of catgut inserted to control a bleeding point. The bladder was sewn up as described, and was not drained. The abdominal wound was completely closed. The patient made an uninterrupted recovery, the wound healing by first intention. He passed urine voluntarily the evening of the operation, and continued to do so at frequent intervals. The urine was slightly tinged with blood for the first few days. On June 24th I again examined his bladder with the cystoscope, and could see the line of incision soundly healed, while the

FIG. 5.



Second row of suture closing the bladder. (Mayo, *Annals of Surgery.*)

site of the growth was marked by a small area of granulations. He went home the next day—that is, on the twenty-sixth day after operation, and was then able to retain his urine for five hours.

*Note.*—Since writing the above I find that Richardson in 1895 successfully performed transperitoneal cystotomy on two cases for the removal of large calculi on which the bladder had firmly contracted.[2]

KING'S COLLEGE (UNIVERSITY OF LONDON).—A course of four lectures on Recent Progress in Physiological Chemistry will be delivered in the Physiological Laboratory, King's College, London, by Dr. Otto Rosenheim, at 4.30 P.M., on alternate Mondays, beginning Jan. 30th. The subjects dealt with will be Inorganic Substances, Carbohydrates, Fats, Proteins, Lipoids; the Chemistry of Colloids and Enzymes. The lectures are free to all members of King's College, to all students of medicine, to all internal students of the University of London, and to medical men on presentation of their cards

# PUERPERAL CONVULSIONS, OR ECLAMPSIA,

AT THE LIVERPOOL WORKHOUSE HOSPITAL.

BY WILLIAM ALEXANDER, M.D.R.U.I., F.R.C.S.ENG.,

VISITING SURGEON.

THERE is no disease where the results of treatment are so unsatisfactory and so uncertain as in puerperal eclampsia, and in few diseases are there so many, so varied, or such opposite methods of treatment. This arises from the imperfect knowledge of the disease that we possess and from the apparent facility with which serious cases rapidly improve, or the rapidity with which apparently favourable cases become worse or unexpectedly prove fatal. Hence the undue advocacy of remedies which have been followed by recovery in apparently hopeless cases by some medical men, and the low opinion of the efficacy of the same remedies by other medical men who have used them in apparently favourable cases that, nevertheless, turned out unsuccessfully.

A feeling of uncertainty is universal amongst medical men when called to treat a case of eclampsia, and a very guarded prognosis is always given. The necessity of judicious antepartum treatment is always insisted on, and no doubt the management of the pregnant woman is of great importance; but here again we have no certain methods of treatment that will always ward off eclampsia. Many years ago the writer had a share in the treatment of a lady who was attacked by albuminuria and œdema at mid-term. All the resources of medical knowledge were used to ensure the disappearance of the symptoms before delivery, and success, as far as the disappearance of albumin was concerned, was obtained and safety seemed assured. Nevertheless eclampsia set in post partum, and death took place in spite of all our efforts. On April 3rd, 1906, a woman, aged 19, a primipara, presented herself in the maternity ward suffering from œdema and albuminuria, and 7 months pregnant. She was sent to the general ward to be dieted, but went out against advice. We heard afterwards that she had been delivered naturally, after which the œdema disappeared.

Miss Aldworth, the sister in charge of the maternity wards, has made out for me a statement of the condition of the urine in the patients admitted there for the past five years. From this statement we find albuminuria present in 57 cases, accompanied by general œdema in 25 cases, accompanied by œdema of the lower extremities in 13 cases, albuminuria without any œdema in 19 cases. The quantity of albumin varied from a trace up to 16 grammes. All these cases were delivered safely without any eclampsia, but headaches, blurred vision, stupor, &c., are recorded in a few cases. Many of them were delivered without any preparation, but where possible salines and simple diet were prescribed, so far as time permitted.

The failure of preparatory hygienic measures to save from eclampsia the lady first referred to, and the impunity with which so many cases were delivered safely under the same apparent conditions, show that with the utmost care we cannot always avoid a catastrophe. Nor do carelessness and indifference always lead to one.

Below are brief notes of 38 cases of eclampsia.

### *Eclamptic Cases in Lying-in.*

CASE 1.—Admitted Oct. 13th, 1903. Aged 25; married; primipara. Condition on admission: Os nearly fully dilated; trace of albumin in urine. Subsequent course: Fits began during second stage; had three; then chloroform administered and patient delivered with forceps of healthy child. Fits continued after delivery, patient having 11 during the next 12 hours and being semi-comatose between. Treatment: (*a*) Before delivery—blanket bath. (*b*) After delivery—(1) Enema; (2) potassium bromide (24 grains); (3) later, oxygen inhalation frequently. Progress: Fits ceased after 12 hours. Became more conscious; headache complained of. Fair quantity of urine passed. Bowels kept well opened with saline purgatives. Made good recovery and discharged in 13 days with still a slight trace of albumin in urine.

CASE 2.—Admitted Dec. 30th, 1904. Aged 25; married; primipara (stillborn) and one miscarriage. A week previous to admission face and hands began to swell. Condition on admission: Unconscious; os not dilated; urine loaded with albumin. Subsequent course: Two fits occurred during first stage; none during second. Natural delivery (child premature, decomposed). One fit during third stage and four during next eight hours. Treatment: (*a*) Before delivery: Bath; enema. (*b*) After delivery: (1) Dry cupping over kidneys; (2) pilocarpine nitrate (⅓ grain hypodermically four hourly); (3) oxygen inhalation frequently; (4) vapour bath; (5) potassium bromide (24 grains four hourly); (6) pulv. jalapæ co. (1 drachm, repeated in 12 hours); (7) copious enema. Progress: Fits ceased eight hours after delivery; patient continued drowsy. Milk and barley-water by mouth. Urine remained scanty and loaded with albumin for next 24 hours. Next day urine greatly increased, and less albumin. Recovery uninterrupted. Albumin disappeared from urine.

CASE 3.—Admitted Dec. 31st, 1904. Aged 23; single; primipara. Condition on admission: Os dilated to size of sixpenny-piece. Weak pains. Subsequent course: Delay in second stage. Chloroform administered and patient delivered by forceps of healthy child. Five hours after delivery she had a fit, a second after eight hours, and a third five hours later. Urine loaded with albumin. Treatment: (1) Chloral (15 grains), potassium bromide (24 grains), latter repeated four hourly; (2) calomel (5 grains); (3) cupping to kidneys; (4) pilocarpine nitrate ⅓ grain hypodermically); (5) oxygen inhalation. Progress: Had no more fits after third. Condition improved rapidly in next few days, urine becoming more copious and containing less albumin. Good recovery.

CASE 4.—Admitted March 19th, 1905. Aged 23; single; primipara. Fits began seven hours before admission—nine altogether. Condition on admission: Comatose; anasarca. Subsequent course: Had 11 fits in five hours. Urine scanty, loaded with albumin. Five hours after admission bougies were inserted into uterus; labour came on in 40 hours; no fits during this time. Patient delivered seven hours after labour began of stillborn, decomposed child. Treatment: (1) Vapour bath; (2) ice-bag to head; (3) pilocarpine nitrate (1/10 grain); (4) hot pack; (5) saline enema 1 pint. Progress: After delivery patient continued comfortable for 60 hours, when she had two slight fits in succession. A hot pack was given, and no further fits occurred. Urine during next few days increased in quantity, and the albumin decreased. Patient made good recovery.

CASE 5.—Admitted April 9th, 1905. Aged 36; married; V.-para. Had had gastric trouble for 14 days before admission. Fits commenced 13 hours before admission, several occurring. Condition on admission: Semi-comatose. Labour just commenced. Subsequent course: During first stage (which lasted 11 hours) patient had two fits. Second stage two hours and had no fits; natural delivery; child small, premature. Patient continued restless and delirious all day. Urine very scanty with trace of albumin. Treatment: (*a*) Before delivery—(1) Magnesium sulphate (90 grains three hourly); (2) enema; (3) saline injection (four hourly); (4) oxygen frequently. (*b*) After delivery—Hot pack, repeated after 16 hours, and again 9 hours later. Progress: Had no fits after delivery. Continued fairly well for three days, then became worse, incontinent, &c. Dull, listless. Temperature rose to 103° F. Died six days after delivery from stupor and asthma. Necropsy not granted.

CASE 6.—Admitted Dec. 18th, 1905. Aged 19; single; primipara. Condition on admission: Face, hands, abdomen, and legs swollen. First stage of labour well advanced. Subsequent course: Six hours after admission had a fit. Chloroform administered and patient delivered by forceps of full-term stillborn child. An hour later had a second fit. Slept well afterwards. Urine scanty; loaded with albumin. Treatment: (1) Enema, bath; (2) tr. scillæ (24 minims), spir. æth. nit. (24 minims), pot. acetat. 6 grains three hourly; (3) chloral (60 grains per rectum); (4) oxygen frequently; (5) calomel (5 grains), pulv. jalapæ co. (20 grains); (6) vapour bath. Progress: After second fit continued much better. Improved daily. Urine rapidly increased and albumin decreased. Uninterrupted recovery.

CASE 7.—Admitted Feb. 1st, 1906. Aged 22; single; primipara. Condition on admission: Slight pains. Os not dilated. Trace of albumin in urine. Subsequent course: Shortly after admission patient had a fit. During first stage (which lasted 12 hours) patient had 20 fits. An hour later delivered naturally of twins, having three fits during second stage. During next four hours she had 11 fits. Became incontinent, cyanosed, unconscious. Treatment: (1) Bath, enema; (2) calomel (5 grains), pulv. jalapæ co. (25 grains); (3) oxygen frequently; (4) hot pack; (5) morphia (¼ grain), atropia (1/75 grain), hypodermically; (6) croton oil (1 minim); (7) cupping over kidneys; (8) vapour bath; (9) potassium bromide (24 grains), chloral (30 grains per rectum); (10) venesection (14 ounces withdrawn); (11) ice-cap to head. Progress: Fits ceased four hours after delivery, leaving patient unconscious and cyanosed. Given liquor strychninæ hydrochloride (3 minims) and digitalis (1.50 grain) hypodermically, brandy (1 ounce). Temperature rose to 105·4° F., so was ice sponged. Saline enema (20 ounces) given. Three hours later strychnine and digitalis repeated. Breathing now difficult; mustard poultice given. Urine very scanty. Condition slightly improved during next 12 hours. The patient slowly grew worse and died next day. No necropsy allowed.

CASE 8.—Admitted Oct. 3rd, 1906. Aged 18; single; primipara. Condition on admission: Slight œdema of legs; small quantity of albumin in urine. Os dilated to size of a shilling. Subsequent course: First stage finished nine hours after admission. Two hours later delivered naturally of healthy, full-term child. Labour in all respects seemed normal. One hour after delivery patient had eclamptic fit, followed by a second and a third at intervals of 15 minutes. Did not regain consciousness between the fits. Treatment: (*a*) Before delivery—(1) Enema; (2) magnesium sulphate (90 grains, four hourly); (3) milk diet. (*b*) After delivery—(1) Copious enema; (2) oxygen frequently; (3) mist. diuretic. (1 ounce, three hourly). Progress: After the first three fits had passed off the patient became quite conscious and spoke rationally. Three hours after third fit she had a fourth, and then frequent attacks. Recovered completely. Went out quite well.

CASE 9.—Admitted Dec. 18th, 1907. Aged 22 years; single; primipara. Condition on admission: Os partially dilated. Urine contained large quantity of albumin. Subsequent progress: Delivered of healthy child three hours after admission; labour normal. Seven hours after delivery patient had an eclamptic fit and two more at intervals of ten minutes; conscious in interval. Transferred to surgical wards where she had five more fits in one and a half hours. After this she remained comatose and died 28 hours after delivery. Necropsy: Œdema of lungs.

CASE 10.—Admitted Jan. 19th, 1908. Aged 20; single; primipara. Condition on admission: Feet, legs, and abdomen œdematous; face puffy and cyanosed. Os partially dilated. Urine contained small quantity of albumin. Subsequent course: Six hours after admission delivered naturally of healthy child. Seven hours after delivery patient had an eclamptic fit, and during next ten hours had seven more. Treatment: (1) Copious enema saponis; (2) magnesium sulphate (1½ drachms hourly); (3) hot pack (repeated in four hours); (4) morphia (¼ grain hypodermically); (5) ice cap to head; (6) potassium bromide (12 grains); (7) saline injection (1 pint); (8) mustard cloths to legs; (9) thyroid tabella (gr.v., one thrice daily). Progress: Slightly improved; quite conscious. Transferred to surgical wards. No more fits after this and no further treatment. Uninterrupted recovery.

CASE 11.—Admitted June 12th, 1909. Aged 33; single; primipara. Condition on admission: Os slightly dilated; restless; no pains. Subsequent course: Delivered naturally 22 hours after admission. After delivery remained comfortable for two hours, when she had a fit. Urine contained small quantity of albumin. Treatment: 1. Before delivery, for restlessness—nepenthe (15 minims). 2. After delivery, when fit occurred—(1) calomel (5 grains); (2) potassium bromide (24 grains); (3) haust. chloral (15 grains); (4) enema saponis (20 ounces) with glycerine (1 ounce); (5) milk diet, barley water. Progress: No fits occurred after the one mentioned above. No further complications. Recovery uninterrupted.

CASE 12.—Admitted Jan. 25th, 1910. Aged 22 years; single; primipara. Condition on admission: Unconscious. Had had eight fits before admission. Os dilated to size of a shilling. Moderate albuminuria (4 grammes). Subsequent course: Five minutes after admission patient had a severe fit. One hour after admission chloroform was administered, the os dilated with the fingers, leg drawn down, and patient delivered of stillborn, decomposed child. Second child decomposed, also delivered by traction. Placenta removed manually. Douched. Patient remained semi-conscious for three hours after delivery, when she died suddenly. Treatment: (1) Enema; (2) hot pack. Necropsy: Slight tear of cervix. Large clot in right auricle attached to tricuspid valve.

CASE 13.—Admitted July 25th, 1910. Aged 33; single; primipara. Condition on admission: Bowels not moved for five days. Feet and legs œdematous. Os slightly dilated. Subsequent course: Ten hours after admission patient had a fit. Urine scanty, loaded with albumin; contained blood. Fits continued at intervals of about one and a half hours for seven hours (five fits). After the first three patient was conscious; after the fourth she did not regain consciousness. After the fifth she suddenly changed, became ashen in colour, extremities cold (and apparently in dying condition). She was delivered an hour after the fifth fit of stillborn child. Two hours after delivery she had a slight fit, only twitching on right side. She now became comatose, with apparent paralysis of left arm and leg. She continued much the same all this day. Next day the temperature rose to 106° F., pulse rapid and weak, and she died comatose. Urine was suppressed last 48 hours. Treatment: (1) Enema saponis; (2) bromide of potassium (½ drachm), chloral (15 grains); (3) hot packs, two in succession; (4) chloral (15 grains per rectum); (5) saline injection per rectum; (6) chloroform. Necropsy: Hæmorrhage into ventricles and right corpus striatum. Lungs slightly œdematous. Kidneys congested.

CASE 14.—Admitted Sept. 11th, 1910. Aged 20; married; primipara. Fits began two and a half hours before admission, during which time she had seven. Condition on admission: Semi-comatose and as if recovering from a fit. Feet, legs, and lower abdomen swollen and œdematous. Slightly dilated os. Face cyanosed. Temperature 99° F.; pulse rapid, high tension. Urine loaded with albumin. Subsequent course: An hour after admission patient had a severe fit, and an hour later a second. With treatment she had recovered markedly and became conscious but dull. Continued so for about three hours, when she had a very severe fit. Never again became conscious. An hour and a half later she had another fit, became cyanosed, with later very difficult respiration, and died in five minutes, before time was given to empty the uterus. Treatment: (1) Hot pack; (2) morphia (¼ grain); (3) bromide of potassium (24 grains); (4) mustard cloths to calves; (5) hot pack repeated; (6) pilocarpine (⅛ grain hypodermically); (7) bromide of potassium (1 drachm per rectum); (8) digitalin 1/100 grain hypodermically); inhalation of chloroform. Necropsy: Intense congestion of surface veins of brain. Excess of fluid over motor areas. Other organs apparently healthy.

CASE 15.—Admitted June 19th, 1901. Aged 31; single; II.-para. Very anæmic and debilitated. Normal delivery; child premature. Fits began five hours after delivery. Treatment: (1) Enema saponis; (2) chloral hydrate (1 drachm per rectum); (3) brandy. Recovery.

CASE 16.—Admitted May 21st, 1903. Aged 28; single; primipara. Fits began seven hours before admission. Condition on admission: Unconscious. Urine almost suppressed and contained abundant blood and albumin. Subsequent progress: Continued unconscious after admission for two days. Delivery took place two hours after admission. During this time she had nine fits. Child stillborn. Treatment: (1) Morphia (¼ grain hypodermically); (2) oxygen frequently by inhalation; (3) pulv. jalapæ co. (1 drachm); (4) enema; (5) ether (15 minims hypodermically two-hourly); (6) cupping over loins. Progress: As stated above, patient remained unconscious for two days after delivery, then showed marked recovery. Died from syncope five days after delivery.

CASE 17.—Admitted Oct. 12th, 1901. Aged 16; single; primipara. Progress: Child born three hours after admission. Presentation transverse. Chloroform administered and version performed. Child full term—stillborn. Before delivery patient had three fits. After delivery fits occurred every half hour for eight hours, patient remaining unconscious between them. Albuminuria. Treatment: (1) Potassium bromide (12 grains), chloral (15 grains, three hourly); (2) oxygen inhalation; (3) soap and water enema; (4) nutrient enemata; (5) ice-cap; (6) morphia (¼ grain hypodermically, four hourly); (7) calomel (⅛ grain on tongue every hour). Progress: 12 hours after delivery patient regained consciousness. After this uninterrupted recovery.

CASE 18.—Admitted April 13th, 1902. Aged 29; married; primipara. Had had fits for three days before admission and had been unconscious for 16 hours. Delivered naturally three hours after admission. Twenty minutes after delivery had a fit and became comatose. Urine loaded with albumin. Treatment: (1) Morphia (⅛ grain hypodermically); (2) potassium bromide (1 drachm per rectum); (3) rectal feeding. Progress: After delivery patient became comatose. Temperature rose gradually during next 24 hours to 103·8° F., when patient died.

CASE 19.—Admitted Dec. 17th, 1909. Aged 15; primipara; single. Delivered of a male child five hours before admission. Had one fit previous to confinement and five after; labour natural. On admission patient was unconscious and cyanosed. Urine: 10 ounces were drawn off; traces of albumin. Perineum lacerated. Treatment: (1) Hot pack; (2) mist. magnesii sulphatis; (3) croton oil (2 minims); (4) hypodermic morphia (3 minims, to be repeated in three hours if fits continue); (5) ½ pint hot saline per rectum; (6) bromide of potassium (24 grains four hourly); (7) tr. opii (10 minims four hourly); (8) saline (1 pint four hourly per rectum till attack diminish); (9) sinapisms to legs and feet; (10) ice cap to head. Result: Well on Dec. 29th.

CASE 20.—Admitted Feb. 19th, 1909. Aged 21; single; primipara. Taken suddenly ill at 5 P.M. Had nine fits in the hour before admission to hospital, and one after admission. Unconscious all the evening. Os dilated; girl born by forceps at 10 P.M. Baby normal, 6 pounds 4 ounces. Temperature rose to 103·4° F., and pneumonia set in from which patient died on Feb. 28th. Urine scanty and loaded with albumin; only one ounce of urine in bladder on admission. As fits ceased on admission attention was directed to the chest.

CASE 21.—Admitted July 26th, 1903. Aged 21; primipara; single. Confined at 2 o'clock the morning of admission. Was well till 7 o'clock when she complained of severe headache. At 8 A.M. friends saw her in a fit which lasted a few minutes and recurred at intervals of 20 to 30 minutes till her admission to hospital at 3 P.M. Patient was unconscious then, and had fits at 3.30, 4, and 4.30. She was unconscious till 8 P.M., when she regained consciousness but appeared dazed. From 4.30 to 8 P.M. rather restless, trying to get out of bed. At 8.30 P.M. fell asleep and slept till 12 o'clock when she became very restless and unmanageable and had to be towelled. After this she slept. Next morning she was much better. Urine 1018; albumin ¼. Treatment: Chloral and bromide, pilocarpine, enema aperient, milk diet. Patient febrile and restless for a few days, albumin becoming less and less, and disappearing on August 12th. Patient discharged well on the 22nd.

CASE 22.—Admitted Oct. 7th, 1907. Aged 22; primipara; single. Admitted at 3 o'clock in the afternoon, having been confined naturally that morning at 4 o'clock of a healthy child. At 11 o'clock she began to have fits and had seven up to the time of coming to hospital. After admission she had 11 in six hours. The face was much cyanosed and breathing stertorous between the fits. Urine scanty and loaded with albumin. Treatment: Venesection to 12 ounces; saline injections per rectum; bromides; morphia; hot packs. Patient died 1.15 P.M. on the 8th.

CASE 23.—Admitted April 13th, 1909. Aged 29; married; primipara. Patient's friends found her unconscious on the floor of her bedroom and brought her to the hospital. They said she had been suffering from headaches for several days before. On admission she was unconscious and cyanosed. Had a fit every hour for five hours. Urine drawn off (3 ounces) was loaded with albumin. In the evening labour commenced; os dilated naturally and child delivered by forceps. Fits had ceased before delivery. Treatment generally: Hot packs, enema saponis, oxygen inhalation, chloral (30 grains per rectum), stupes to chest, saline rectal injections, morphia, hot drinks, mist. magnesii sulphatis, ergotin for subinvolution. Result: Patient was discharged well on June 15th.

CASE 24.—Admitted Oct. 6th, 1899. Aged 20; single; primipara. Delivered naturally. Eclampsia set in on the eighth day of the puerperium. Urine was of specific gravity 1040 and loaded with albumin. Fits only lasted two hours; no œdema. Treatment: Poultices over the loins, salines internally, pulv. jalapæ co. Recovery was as rapid as the onset and the patient was discharged on Nov. 6th, cured.

CASE 25.—Admitted June 22nd, 1910, at 11 P.M. Aged 21; single; primipara. Condition on admission: Legs and ankles œdematous; face swollen. Urine contained moderate quantity of albumin. Had twitchings of arms and face, with vomiting. Subsequent course: Twelve hours after admission patient was delivered naturally of mature infant. Albumin gradually lessened and 11 days later had completely disappeared. No other complications. Convulsive twitchings ceased after delivery; no treatment necessary. Patient discharged on July 8th quite well.

CASE 26.—Patient, aged 32, was admitted to surgical wards Sept. 12th, 1910. Completely unconscious and with persistent twitching in right arm and hand. She was V.-para and was confined ten days before admission. The previous day she began to have fits which were diagnosed as eclamptic. The convulsions were sometimes on the right side and sometimes on the left. She became unconscious gradually, which deepened into coma before admission. When she came under observation the urine contained albumin and the twitching was entirely confined to the right arm and hand. In the afternoon of the 12th I trephined over the left motor area and found a collection of bloody serum (1 drachm) in a small, shallow, bowl-shaped depression of the convolutions beneath the arachnoid. This was let out, when the brain beneath was found to be dark-red in colour. The depression was drained and the wound closed. She had one slight attack of twitching in the evening, but none after. She never, however, recovered consciousness and died in 24 hours, the temperature rising gradually to 104·8° F. at the time of death.

A post-mortem examination showed the seat of the operation [wound quite aseptic and so was the brain. There was considerable congestion of the lungs; the uterus was healthy, but the brain in both motor areas was the seat of effusion of blood that permeated the whole thickness of the convolutions and involved the left side more deeply than the right. The vessels, especially the veins on the surface of the brain, were gorged full of blood.

CASE 27.—Patient, aged 22, primipara, single; admitted on June 29th, 1880; died on July 2nd. Cause of death coma after eclampsia. Infant died on July 6th from debility.

CASE 28.—Patient, aged 21, primipara, single; admitted on Jan. 13th, 1882; delivered naturally on Jan. 14th, male child. Eclampsia during labour and the day after. Discharged cured on Jan. 28th.

CASE 29.—Patient, aged 19, primipara, single, was admitted on March 2nd, 1882; delivered naturally on March 6th of a female child who lived for five days. Mother suffered from eclampsia and was treated by chloral, having 20 draughts of that drug in the 84 hours during which she had the fits. Recovered completely.

CASE 30.—Patient, aged 24, III.-para, was admitted on Feb. 23rd, 1886; delivered naturally 15 minutes after admission of a male child. Eclampsia occurred, and was treated by baths and chloral. Recovered quickly and completely.

CASE 31.—Patient, aged 31, V.-para, was admitted on May 28th, 1893. She was delivered next day, breech presentation, of a macerated fœtus; eclampsia during third stage; labour assisted; post-partum hæmorhage. Rapid and complete recovery; ergot, chloral, &c.

CASE 32.—Patient, aged 19, primipara, single, was admitted on Jan. 10th, 1895; delivered naturally five hours after admission. Eclampsia after; choral, poultices to loins, &c. Recovery rapid and uninterrupted.

CASE 33.—Patient, aged 22, single, primipara, was admitted on April 23rd, 1897; delivered naturally 4½ hours after. Eclampsia at end of labour. Temperature rose to 99° F. Recovered rapidly and easily.

CASE 34.—Patient, aged 19, primipara, single, was admitted on

Jan. 13th, 1888; delivered naturally 7 hours after of a male, stillborn. Uræmic convulsions for several hours. Chloral. Recovery excellent.

CASE 35.—Patient, aged 22, primipara, was admitted on June 21st, 1888; delivered naturally on the 22nd of a male child. Eclampsia with albuminuria post partum. Sent to general wards, where a rapid recovery resulted.

CASES 36 AND 37.—Two cases are tabulated in 1887 as having suffered from eclampsia; both recovered, but no particulars can be found.

CASE 38.—In 1882 a death from puerperal convulsions is reported on the third day; no details to be found.

CASE 39. *A supposed eclamptic.*—Patient, aged 20, primipara, single, was admitted to the lying-in wards on the morning of Oct. 21st, 1886, with convulsive seizures of a general kind, but without œdema or albuminuria. In the evening she had become unconscious, but the child was alive. Temperature over 101° F. Patient had been observed to be stupid and queer for a few days, getting up at night and drinking out of the water-jug, but no one thought much of it. When I saw her in the evening she was quite unconscious, the baby being still alive. The os was not dilated, labour not having commenced. Without requiring any anæsthetic the uterus was opened through the abdomen, and a living child extracted. The woman never moved during the operation and died soon after. A post-mortem examination revealed suppurative meningitis; a layer of yellow pus a quarter of an inch thick covered the whole encephalon. The child was adopted.

From a study of the notes of the cases recorded above, which were kindly collated for me by my house surgeon, Dr. William Messer, it will be seen that 30 were primiparæ and 5 multiparæ (I.–V.-para), 3 being unknown. The patients were married in 9 instances and single in 26, with 3 unknown. In 4 cases the urine contained only a trace of albumin, and 2 of these proved fatal. In one of these fatal cases the urine was scanty, but in the other no mention is made of the quantity. In the third case of scanty albumin it is recorded that the quantity was abundant. This patient recovered, and so did the fourth. The quantity of albumin has no direct relation to the gravity of the case, but the quantity of the urine has a very close inverse relation with the seriousness of the disease. In all the other cases the amount of albumin has been considerable; in many the urine was loaded. In one case the urine was sanguineous.

*Onset of attacks.*—In 5 cases the fits began before parturition set in; in 5 cases during the first stage of labour; in 6 cases during the second stage; in 1 case in the third stage; in 15 cases the attacks began post-partum, and in 1 case we have no clue to the time of onset. Of the post-partum onset the times varied from a few minutes after the termination of labour to as much as eight days after. In only 5 cases did the fits cease on delivery, and in one of these the fits had ceased before delivery.

If we take into consideration the great number of cases (15) where the fits began post-partum and add to them the large number where the attacks continued after delivery took place, it does not seem as if the presence of the child in the uterus had so much influence on the course of the disease as is supposed. We will revert to this question again in considering treatment.

*Mortality.*—Of the 38 cases recorded above the mortality was 34·2 per cent. The disease seems with us to be very largely on the increase, and the mortality has increased very much in proportion. For instance, during the 20 years 1880–99 inclusive we have on record only 12 cases that came into the lying-in wards, with a mortality of 2, or 16·6 per cent. During the years 1900—Oct. 15th, 1910 we have had 26 cases, with a mortality of 11, or exactly 42·3 per cent., over twice the total number and nearly three times the mortality. During the 20 years the 12 eclamptics occurred amongst 5978 obstetric cases, or an incidence of 1 in 498. During the 10–11 years the 26 cases occurred amongst 4055 cases, or an incidence of 1 in 156.

Is this increased frequency of the disease due to an increased sensitiveness of the nervous system in the young girls whom the disease most frequently attacks, or is it due to increased frequency of albuminuria? Until I made up the statistics of albuminuria in all the admissions for the past five years I had no idea that albuminuria was so common amongst the patients generally. We have no statistics during the first 20 years, when eclampsia was infrequent, to show whether albuminuria was less common amongst the bulk of obstetric patients then than it is now. Examination of all urines since 1906 showed the presence of albumin in 57 cases out of 2099, or 1 in 36·9. Eclampsia actually occurred in 15 cases during the same years, and if we add these to the 57 œdematous and albuminuric cases we have 72 cases liable to eclampsia amongst 2099 deliveries. The actual and potential eclampsias in 1906 were 10; in 1907, 12; in 1908, 5; in 1909, 15; and for 10 months of 1910, 23. The actual eclampsias in the same years were 2, 2, 1, 5, and 4 respectively. We may, therefore, congratulate ourselves that things were not very much worse, but such numbers of albuminuric and œdematous cases add tremendously to the anxieties of those in charge of the lying-in wards.

*Treatment adopted.*—A perusal of the brief notes of the cases in which the treatment is recorded will show the methods of treatment generally adopted.

The hastening of delivery was adopted in only 7 cases. In 5 cases forceps were used, and one of these was suffering from pneumonia at the time and died from that disease. In one case artificial dilatation of the os and version effected the delivery of a decomposed fœtus. The mother died suddenly a few hours later with a cardiac clot. Another transverse case recovered after delivery by version.

The delivery was natural in 29 cases. In one case labour had not really commenced, and the patient was so much better after admission that operative treatment was postponed. Some sudden severe attacks carried her off before the surgeon could be communicated with. The vessels of the encephalon were intensely congested and much fluid was found in the subarachnoid.

In the 28 natural deliveries one had recovered and was three days well, when she became listless and apathetic and died from asthenia. No necropsy was made. A second case was delivered of twins and had most severe attacks post partum; venesection and salines failed to relieve. A third died from œdema of the lungs, as verified post mortem, a disease that affects ordinary epileptics. A fourth died from apoplexy, with hæmorrhage into the ventricles and into the right corpus striatum. A fifth case had recovered completely and died from syncope 5 days after delivery. A sixth case had fits three days before admission. The temperature after delivery suddenly rose to 103·8°, and the patient became comatose and died rapidly. No post-mortem examination could be obtained. A seventh case had post-partum attacks. Venesection was performed, but the patient died. An eighth case had hæmorrhages into the grey matter of the motor area of both sides of the encephalon.

Two deaths occurred in 7 cases of operative emptying of the uterus, or 28·5 per cent.; and 9 deaths in 29 cases where nature was not interfered with, or 31 per cent. If we take the circumstances of the cases into consideration I think it will be conceded that very little difference can be made between the result of the two methods of treatment, and a study of the cases will show that the presence of the child in the uterus does not seem to have much influence either on the onset, the cessation, or the continuance of the fits.

Routine treatment consisted of *purgatives*, such as jalap, magnesium sulphate, calomel, and croton oil. *Diaphoretics.* Blanket bath, hot packs, pilocarpine, hot poultices over kidneys, saline diuretics, hot drinks. *Nerve sedatives:* Bromides, morphia, chloral in varied doses; fomentations to loin, dry cupping over kidneys, venesection of arm, ice to head and thyroid powder, chloroform and oxygen inhalations. Of these the bromides, morphia, and chloral are tried friends that have been freely used. The only drawback to their liberal use is the reflection that in case of failure the death may have been due to excess of medication. Fomentations to the loin, dry cupping, blanket baths, and hot packs are useful and always harmless. Pilocarpine is, I think, of great value. Thyroid was used in one case, but she was recovering when it was given, and we have no statistics of a sufficient series of cases of all kinds treated by this drug to show its real value. Venesection failed in the two cases in which it was adopted and seemed to hasten the end. Saline injections, either into the rectum or the subcutaneous tissues, are both of great value. Rectal salines, in conjunction with oxygen inhalations, have produced some startling improvements in many of our cases.

We will not here enter upon the pathology of eclampsia, but we think there is no doubt that in that disease there is intense congestion of the cerebral vessels and effusion of serum or of serum and blood over the cerebral convolutions, and sometimes rupture of cerebral blood-vessels. All of these incidents are well illustrated in the above cases. Case 39 is interesting for its simulation of eclampsia.

Liverpool.

# THE RÔLE OF AUTO-INOCULATION IN MEDICINE:

## A PLEA FOR ITS RATIONAL EXTENSION.[1]

BY CLIVE RIVIERE, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN, EAST LONDON CHILDREN'S HOSPITAL; PHYSICIAN TO OUT-PATIENTS, CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

MY thesis readily divides itself into two arguments, which may be briefly stated as follows: Firstly, that a form of vaccine-therapy has long been applied, unconsciously but successfully, by physicians in their treatment of infective processes in the body. Secondly, that the success attending this practice might be increased if it were developed into a conscious aim under the guidance of recent knowledge of the subject of treatment by vaccines.

### PART I.—*Empirical Treatment of Infective Diseases an Example of Vaccine-therapy.*

You will remember how gratified, as well as surprised, was M. Jourdain in Molière's comedy when it was discovered to him that for 40 years, unknown to himself, he had been talking "prose." When, however, it was pointed out to the medical profession that they had been practising the art of vaccine-therapy for generations, not knowing what they did, the initial surprise was followed, perhaps, by a feeling of annoyance. It was annoying to see how far empiricism had outstepped rational medicine and to find so late in the day an explanation of the success which had certainly followed the poulticings and fomentings of the past. M. Jourdain soon proved that the prose he had used for so long in ignorance was good prose, and the science of the *maître de philosophie* failed to improve upon it. So far the same might be said for medical practice—the fomentation is a good remedy, but a knowledge of the principles which govern its action does not appear at present to have improved its application. It is to be hoped, however, that a different experience to M. Jourdain's is to follow, and that recent knowledge will now enable rational medicine to steal a march on empiricism.

Up to the present the local application of heat by poultices and fomentations has stood as the example of "empirical vaccine-therapy." To these might be added numerous other homely, and sometimes barbarous, remedies directed to the same end, such as the sucking of infected wounds, and the dressing of these with hypertonics and irritants, such as salt and pepper. All these remedies reinforced nature's method of meeting infection by an increased blood-supply to the offended part. But it is my object to show that the unconscious augmentation of irrigation and auto-inoculation did not stop with these simple remedies, but that the physician has held in his hands the weapons of the vaccine-therapist from time immemorial, and has, indeed, used them, too, with no inconsiderable success.

Nature was the earliest "vaccine-therapist." The processes by which infections are naturally overcome in the body form the basis on which the science of vaccine-therapy is being built up. As soon as the invader "lands" in a tissue there is a call for more blood, blood plasma acts on the microbe and its toxins, destroying them both by chemical processes (oxidation, hydration, dehydration, &c.) and by the action of specific antibodies, and leucocytes rush out to ingest the foe. If this proves insufficient further antibodies are formed in response to the toxins carried over the body in the blood stream, and the resistance of the plasma bathing the lesion is thereby raised.

We thus have two natural processes to study and imitate: 1. "*Irrigation*" of the infected area with plasma and leucocytes, and this by itself may be enough to cure a mild invasion. 2. *Auto-inoculation*, or the washing of the bacterial products into the blood stream to stimulate in the tissues the formation of antibodies specific to the invading micro-organism. These are the processes (other than the injection of vaccines) which the physician can direct with success, and it is this "natural vaccine-therapy" that was exploited with success in the time-honoured practice of applying heat (poultices, &c.) to an inflamed area. By this means not only was irrigation assisted, but such irrigation, itself of value, necessarily led to an increase of that auto-inoculation on which the improved resistance of the body depends. Such an effect is obvious so far as the poultice is concerned, but it is not so obvious, and it is my purpose to point out, how also the drug treatment of infective diseases may have depended for its success, so far as it has been successful, on a similar encouragement of these processes of "irrigation" and "auto-inoculation."

My contention will best be brought before you by its application to familiar examples. Let us consider infections of mucous membranes, and, in this connexion, turn to bronchitis, where there is general agreement as to the means to be employed.

*Bronchitis.*—It will not be disputed that the classical treatment of bronchial infections, though the outcome of empiricism, is, where thoroughly carried through, highly successful. It consists, shortly, in the giving of the so-called "depressant expectorants" till secretion is abundant, and then changing to the "stimulating expectorants," with perhaps, later on, certain of the balsams or volatile oils. This treatment is based on our experience that abundant exudation is necessary for cure. Abundant exudation implies either plus infection or adequate response, and the relative amount of these two factors in any given case demonstrates itself by the course which the disease takes.

If, now, we inquire into the pharmacological action of the "depressant expectorants," of emetine, of salts of antimony, of apomorphine, of the iodides, what do we find? We find that all these drugs cause a watery exudation through the bronchial mucous membrane. Emetine, antimony, and apomorphine are emetics, the two first through their irritant action on the gastric mucous membrane, the last by its action on the nervous centres in the medulla. Now, profuse secretion from the mucous surface of nose, pharynx, and bronchi is a constant by-product of the act of vomiting, as is also an increase in the sweat, tears, and saliva. But a similar effect is produced, though to a less extent, by subemetic doses of these drugs, and in this manner they become reliable expectorants. When we turn to the iodides we find a different pharmacological action; these substances are excreted through the bronchial and other mucous membranes and cause a watery flow by their local action. In some cases iodine itself is liberated, leading to the more striking irritant effects generally known as "iodism."

Thus it appears that these drugs, the classical standby in bronchitis with scanty exudation, though their mode of action varies, all lead to one result—namely, the bathing of the infected mucous membrane in a protective muco-serum, or, in other words, increased "irrigation." Given a sufficient blood-supply, they cause a rush of fluid through the newly formed mucous cells and glands on to the surface, imitating in an inaccessible area the osmosis we can so successfully obtain in a dry sinus by the local application of hypertonic solutions. Have we not here, also, an explanation of the value of emetics pushed to vomiting point in cases of bronchitis? That the removal of secretion by vomiting is not the sole gain by the administration of these large doses is shown by the benefit occasionally obtained from their use even when vomiting does not occur. Surely the increased flooding of the mucous membrane with healing serum is no small element in this favourable result.

At a later stage of catarrh, or in chronic bronchitis, the blood-supply to the mucous membrane may also be in default. This depends on the general blood pressure, which is generally raised above the normal in chronic bronchitis, perhaps as a compensatory measure. Now are used the "stimulating expectorants," squill and its congeners and ammonium carbonate. These also, like the depressant expectorants, are gastro-intestinal irritants and emetic in full doses, and in virtue of this action increase the secretion from the bronchial mucous membrane. At the same time they raise the general blood pressure by their action as vaso-motor and cardiac tonics, and hence increase the blood-supply to the bronchial tubes by both systemic and pulmonary blood channels.

Thus, again, by our treatment, we are "irrigating" the diseased area, supplying blood serum and perhaps leucocytes to the infected site in imitation of the natural process. When this is considered complete, we attempt to coax the mucous membrane back to conditions of healthy secretion by such mild astringents and stimulants as the volatile oils (copaiba, cubebs, eucalyptus, &c.) and terebinthinates (terebene, &c.).

[1] A paper read before the Therapeutical and Pharmacological Section of the Royal Society of Medicine on Jan. 17th, 1911.

It must be borne in mind, of course, that the peculiar position of the bronchial mucous membrane demands recognition also of a mechanism for the expulsion of secretion, in addition to the repulse of the invader, and to aid this mechanical action the use of drugs acting on the respiratory centre, such as ammonia and strychnine, is sometimes called for.

It will be remarked that most of the drugs we have mentioned are in request for other purposes besides that of expectorants, and it is interesting to note that in their other uses also their action might be interpreted as mainly one of "irrigation." In stomach catarrh we recognise the advantage of an emetic, though we do not always dare subject our patient, unless a child, to so unpleasant a remedy. We talk in this connexion of "emptying the stomach," but may not the most important result achieved be the "irrigation" of the stomach wall which is a necessary accompaniment of emetic action? The efficiency of ipecacuanha in dysentery, and its value in small doses in some catarrhal conditions of the gastro-intestinal tract clearly point to its known action as an "irrigator" of the diseased mucous membrane. Again, the terebinthinates and such volatile oils as copaiba and cubebs have had a recognised province in the treatment of infections of the urinary tract. Such an effect has been shown to have no clear dependence on antiseptic action, and is it not likely that their value has really depended on their irritant properties, or, in other words, on the "irrigation" they have caused? Examples might be multiplied, but I do not wish to waste your time or add to my own responsibility by wandering over too wide a field.

PART II.—*The Advances on Empirical Treatment suggested by a Consideration of the Principles of Vaccine-therapy.*

Now in all the examples we have considered the influence of the physician has been solely in the direction of irresponsible "irrigation." But Nature's armamentarium contains, in addition, the weapon "auto-inoculation," a weapon to be brought into use where "irrigation" alone has failed. The physician has neglected this weapon; he has been an "irrigator" pure and simple, whether with his poultice or in the drug treatment of bronchitis and other infective diseases. To be sure, auto-inoculation has necessarily occurred as the result of his irrigation, but has he directed it? Has he applied his fomentations at such intervals that time may be allowed between for the formation of antibodies? Has he calculated at what intervals he should auto-inoculate his phthisis cases to maintain most successfully their toxin immunity? Has he sufficiently calculated the dangers of hyper-inoculation and a "negative phase"? As a rule he has done none of these things, and it is with the hope of directing attention to the neglect of auto-inoculation in medicine that the present paper is presented to you.

It is hardly necessary in these days to indicate the lines on which the vaccine-therapist works; one must presume that the phases of a vaccination experiment are familiar to all. Suffice it to remind that a sufficient interval must be left between every two inoculations for the "negative phase" of immunity to be passed and a "positive phase" achieved.

It is obvious that the "auto-inoculator" has but one way of achieving his purpose, he can inoculate only *by increasing the blood-supply to the diseased focus*. But by doing so he also "irrigates," so that one act must serve these two purposes, though different considerations govern the indications for "irrigation" and "auto-inoculation." For "auto-inoculation" purposes the act should be *periodic*, to allow time for the formation of antibodies and to avoid negative phases, while for purposes of "irrigation" the more continuous the flow the better. A happy union of these two aims may best be achieved by a strong "auto-inoculation" at certain intervals, and a fair amount of "irrigation" (with, of course, some amount of unavoidable auto-inoculation) maintained between.

Auto-inoculation is open to one disadvantage of a more or less serious nature—namely, the fact that we must auto-inoculate into the blood stream instead of into the tissues. It is, of course, well known that toxin immunity (exemplified in the preparation of antitoxin) is better achieved by subcutaneous than by intravenous injections, and the evidence generally seems to show that the most active formation of bacterial antibodies takes place in the tissues. Bacterial products must necessarily be greatly diluted in the blood stream, and when they reach the tissues by this path are not so fitted to call forth a response as they would be if injected subcutaneously. Nevertheless, this apparent disadvantage accompanies all natural methods of cure, and by auto-inoculation we are but imitating Nature's mechanism. It may be that the tissues conjoining the diseased focus play a large part in this "antibody" formation, but, at any rate, we need hardly fear to follow Nature's lead.

It may be said that every method of treatment suffers certain disadvantages and limitations. Those of the artificial injection of vaccines may be briefly stated as follows:—1. The nature of the causative microbe may be impossible to determine; it may be out of reach and general opsonic tests may be doubtful or misleading. 2. The microbe, though its nature is determined, may be impossible to cultivate outside the body, as may happen in the case of certain strains of influenza bacillus. 3. Many microbes may be at work, and it may be doubtful how far each one is responsible. 4. There is, of necessity, a certain loss of time while the micro-organism is being found and a vaccine prepared.

The use of "auto-inoculation," on the other hand, suffers none of these disadvantages, but shows, to be sure, certain weak points of its own. The following may be cited:—

1. The dose given by auto-inoculation can never be so accurate as where subcutaneous injection is employed. Nevertheless, with a skilled appreciation of the nature of the infection and the response of the individual, the dose can usually be fairly accurately gauged, and readily confirmed by experiment. It may be remarked, in this connexion, that even to "direct" vaccination the dose is to a considerable extent experimental, both the toxicity of the particular strain of organism (which varies greatly) and the reactive power of the patient having to be taken into account.

2. The fact, already mentioned, that auto-inoculation occurs into the blood stream instead of into the tissues.

3. The possibility of doing harm: (*a*) Where in an organ like the kidney with a firm capsule "irrigation" is limited by space, and an increased blood-supply might lead to stasis with suppression of urine and death. (*b*) By the washing out of germs into the blood stream and so generalising a disease; this is seldom, perhaps, a serious consideration, except in the case of tuberculosis, where manipulation of an abdominal tuberculosis (never to be recommended) might lead to such a result. It is obvious that those dangers are not those of the method, but of its abuse in the hands of the careless or ignorant.

4. Localised disease may be so localised that insufficient auto-inoculation may be producible for its cure. Such localisation, on the other hand, may be a bar to successful treatment by the subcutaneous injection of vaccines also, unless special measures for increased irrigation are carried into effect.

It is obvious from a consideration of the weak points belonging to "direct vaccination" and "auto-inoculation" respectively that their provinces do not overlap, that each has its special field of operations, and that they are in a large measure complementary the one of the other. Where disease is mild and recent a control of natural methods should prove sufficient; where infective conditions are unduly prolonged artificial "irrigation" and "auto-inoculation" will cut them short. In chronic conditions, where the disease is within reach of the blood-supply, the same measures should be successful in many cases.

In certain conditions it is obvious that the "direct" injection of vaccines is best. In very localised lesions, boils, or tuberculosis of surface structures, it is readily and successfully employed. In chronic septicæmias it offers the only chance of success, since this must depend on getting the bacterial products into the tissues. In conditions between these extremes there remain many and various infections where auto-inoculation and direct vaccination must strive for the mastery, with some triumphs, I would predict, for the former in the hands of an ingenious "auto-inoculator."

I have pointed out in what manner the time-honoured medical treatment of certain infective diseases falls into line with modern conceptions of natural methods of cure. I now propose to consider what modifications and amplifications of such treatment our recent knowledge of vaccine-therapy suggests.

*Bronchitis.*—To turn once again to examples already given, we found that in bronchitis our attention has been directed too exclusively to "irrigation," and that even here

we have not always known when to stop. In acute and subacute infections of the bronchial mucous membrane "irrigation" is probably all we need consider, and the main point is to see that the flow of serum through the mucous membrane is continued long enough to destroy all the invading germs.

It is where bronchitis tends to become chronic or where repeated catarrhs occur that a conception of the principles of vaccine-therapy may enable us to add "auto-inoculation" to "irrigation" with a more reasonable expectation of success. In either case it appears that the invader has found a secure habitation in the mucous membrane, and the amount of exudation poured out (even where this is considerable) is only sufficient to hold him at bay. Now our means of getting rid of him are two-fold: (1) raising the protective power of the blood by auto-inoculation; and (2) by irrigating the focus in a thorough manner with this plasma of raised power. To auto-inoculate we must irrigate powerfully and that at suitable intervals. Since we do not know the micro-organism with which we are fighting, it behoves us to strike such intervals as are generally suitable, since the inoculation curve does not vary much in length where different organisms are concerned. Once a week where auto-inoculation is large, or twice a week where small, will probably be most suitable, and we may now consider the means at our disposal.

We appear to have at least three means of strongly "irrigating" the bronchial mucous membrane.

1. *By increasing negative pressure in the bronchi* during inspiration a passive congestion of the mucous membrane will be produced, and this may be brought about by the use of a Kuhne's mask or by inspiring rarefied air in the pneumatic cabinet. This may be applied once or twice weekly, but it must be remembered that the mucous membrane may be filled with blood, and yet secretion may be inadequate. For this reason depressant expectorants and perhaps alkalies should be pushed for an interval preceding this treatment, and also given in smaller doses between, to ensure sufficient irrigation in the intervals between each auto-inoculation. To relieve congestion remaining after use of the mask the circulation might be relieved by deep costal respirations. At the same time, counter-irritation of the chest wall and warm air will tend to relieve any passive congestion remaining.

2. *By the use of vapours which are irritant to the bronchial mucous membrane* and so tend to cause an increase of secretion through it. For this purpose creasote and the cresols contained in various preparations may be used, evaporated by heat in a small chamber in which the patient sits, the treatment being preceded with advantage by a short course of depressant expectorants. By this means a considerable temporary irrigation of the diseased area is accomplished, and leads to an auto-inoculation which, applied at the right intervals, should increase the antibodies in the patient's plasma. Here we have, perhaps, an explanation of the action of creasote vapour in bronchiectasis, and of the milder cresols in recurring catarrhs. Do not these act primarily as "irrigators" and "auto-inoculators," their antiseptic action, so greatly lauded, being of quite secondary and insignificant importance?

3. The third method of strong irrigation and auto-inoculation, applicable to bronchitis in children only, is by the weekly or bi-weekly exhibition of emetics till vomiting is produced.

When should we apply these means of auto-inoculation in bronchitis? In recurrent catarrhs they might be used at intervals between the attacks to raise the resistance and destroy the infecting organism. In chronic bronchitis or in bronchitis becoming chronic they should be used just as injections of vaccines are used, at suitable intervals till success is achieved or despaired of.

In cases of chronic bronchitis with freedom during the summer months an attempt might be made during this interval to dislodge the invader at the time when its hold on the mucous membrane was least secure.

Among the three methods here suggested for obtaining auto-inoculation in bronchitis my personal experience is confined to the use of the second only. Some practical success achieved by this means has encouraged me to add to the purely theoretical considerations of my paper these suggestions for their practical application to the treatment of this one variety of infective disease.

It will be readily perceived that the scope of the methods advocated is not bounded by the few examples for convenience considered here. To microbic infections of all regions the same rational means apply, though it is obvious that anatomical and other considerations must here and there change or modify their application. Thus in the kidney and in other organs invested with a fibrous capsule it is obvious that irrigation and its accompanying auto-inoculation can be of but limited extent, and an attempt to augment them beyond a certain point could only lead to stasis. Yet the theoretical considerations should not be disregarded, and even in kidney disease may lead us to new views. Thus, we shall be led to look upon albuminuria in cases of kidney infection (not, of course, in albuminuria of other causation), not as a mere loss of nutritives from the blood, but as the sign of a useful vital function—namely, the irrigation of the diseased focus with healing plasma. Thus (except so far as *plus* albumin implies *plus* infection) we can regard the quantity of albumin with equanimity, and see that its increase (perhaps under our own cautious manipulations) in cases subacute and tending to chronicity may be but a step on the road to cure rather than a sign of further tissue damage. If it were not for its capsule, we are tempted to feel, how much might be done for the kidney in conditions of infection! Such a thought necessarily brings the operation of "decapsulation" into our minds, and we are led to see that, at any rate in theory, this was a step in the right direction.

A glance round the field of medical treatment seems to reveal "irrigation" and "auto-inoculation" at the bottom of many successful empirical methods. The cold bath treatment of enteric fever so successfully employed in America, the use of ipecacuanha and of Epsom salts in dysentery, tar and other irritants in skin inflammations, emetics and purgatives in gastro-enteritis, abdominal massage in tubercular peritonitis—may not all these be claimed as instances of "irrigation" and resulting "auto-inoculation"? Lastly, might we not also improve on these methods, successful only in part, by a fuller recognition of this side of their action, and by directing our attention in future to the periodic spacing and control of that auto-inoculation we have for long unconsciously employed?

Queen Anne-street, W.

## CEREBRAL TUMOUR AFFECTING THE UNDER SURFACE OF THE CORPUS CALLOSUM AND FILLING THE RIGHT VENTRICLE.

BY R. T. WILLIAMSON, M.D. LOND., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN, MANCHESTER ROYAL INFIRMARY.

THE following case is of interest, on account of the situation of the tumour, and of the great difficulty in localising lesions in the regions affected.

The patient, a man, aged 27 years, consulted me at the Manchester Royal Infirmary on account of "tremor, nervousness, and failing memory." His symptoms had been present for a few months. There had been no headache, no convulsions, no paresis of the limbs, and no disease of the ears. His previous health had been good. There was no history of syphilis, alcoholism, or injury to the head.

On examination, when first seen in May, 1910, there was nothing abnormal to be detected on the external surface. The hands and arms presented a fine tremor, somewhat resembling that of Graves' disease; it was noticed on movement of the arms, but it was not an "intention tremor" like that of disseminated sclerosis; it ceased when the hands were supported on any firm object, but it was well marked when the patient held out his arms and hands in front of him, in the extended position. The tremor did not affect chiefly the hand, as in paralysis agitans, but affected the whole arm, producing a fine movement. It differed also from the tremor of paralysis agitans by ceasing when the hands were supported on any firm object. There was also fine tremor of the tongue and of the lips and facial muscles, when the patient was speaking, or when he was asked to show the teeth. The voice was tremulous, but it had not the "scanning" characters of the speech of disseminated sclerosis, and it had not the slurring character of the speech of general paralysis

of the insane, though it resembled somewhat the speech of the latter disease. He complained of failure of memory, of nervousness, and of inability to do his work on account of his mental failure. But when tested he was able to answer questions quite well, to give dates, and make simple calculations without showing any indications of mental confusion. His friends had never noted any "grand ideas," or delusions, or other signs of insanity. He had slept badly for some weeks, but there had been no headache and no vomiting.

There was no paresis of the limbs, face, or tongue muscles. The knee-jerks were present, there was no ankle clonus, the plantar reflexes were present and of the normal flexor type (when the patient was first examined). There was no ataxia, no spastic gait, or other abnormality in the gait. There was no anæsthesia of any form, and no loss of the stereognostic sense; no affection of bladder, rectum, or vertebral column. Examination of the functions of the cranial nerves showed that there was no loss of smell; the pupils were equal and reacted to light and accommodation, and were quite circular in shape; there were no paresis of the ocular muscles and no nystagmus; the fifth, seventh, eighth, eleventh, and twelfth cranial nerves were not affected. There was no hemianopsia, and though vision was but little affected, ophthalmoscopic examination revealed marked double optic neuritis (with much swelling of the optic discs). The heart, lungs, abdominal organs, and urine were normal.

Until the optic discs were examined the diagnosis was indefinite, and the symptoms—tremor of lips, tongue, and facial muscles, tremor of the hands, tremulous speech, failing memory, and history of mental failure—suggested general paralysis of the insane. But the pupils were equal, quite circular in shape, and reacted normally to light and accommodation; and the speech, though tremulous, had not quite the characters of the speech of general paralysis; the mental changes appeared to be simply those of mental failure; and there was no evidence of previous syphilitic infection. On ophthalmoscopic examination one was surprised to find marked double optic neuritis. This and the history of the case suggested intracranial tumour. But there had been no headache and no vomiting. The localisation of the growth was not evident, but a lesion of the frontal region appeared probable at that time.

The man was admitted as an in-patient, under my care, at the Manchester Royal Infirmary on June 4th. His condition was then much the same as on the first examination; but soon afterwards it was found that there was a well-marked Babinski (extensor type) plantar reflex on *each* side, and also a marked Oppenheim reflex on *each* side (extension of the big toe on stroking firmly the inner side of the leg, along the posterior border of the inner surface of the tibia). No true ankle clonus could be obtained. Both knee-jerks were present. There was no paresis of the legs, and no rigidity of the limbs to passive movements. The abdominal and epigastric reflexes were present, and better marked on the right side than on the left. There was no anæsthesia. No affection of the ocular muscles could be detected. On showing the teeth the left angle of the mouth was not retracted quite so much as the right, but the difference was slight.

The optic neuritis was more marked than on the first examination. The temperature was normal; the pulse was slow (60), but regular.

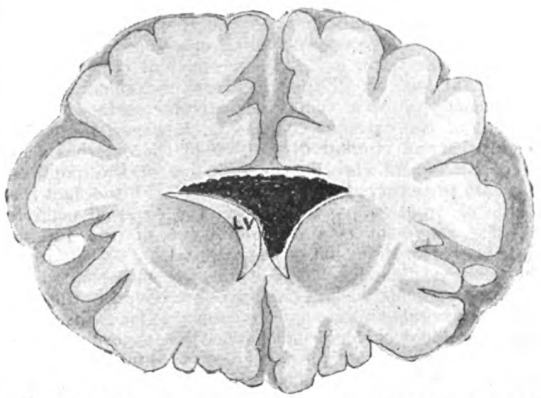
The patient remained very quiet in bed and took little interest in his surroundings. There was no headache at first, but a few days after admission he vomited several times and complained of severe headache. He became drowsy, but when roused could answer questions quite intelligently and could perform all the movements of the limbs which were requested. The drowsiness steadily increased, and for some days he was in a semi-comatose state. Finally, he became quite comatose, and death occurred three weeks after admission.

During the time the patient was in the hospital no paresis of the limbs or ocular muscles developed, and there was only the slight doubtful paresis of the lower part of the left side of the face. The Babinski and Oppenheim reflexes remained well marked on each side, but ankle clonus never developed.

*Necropsy (head only).*—No changes of importance were found on the external surface of the brain, except that the floor of the third ventricle formed a cyst-like projection at the base of the brain. The cerebellum, pons, and medulla were normal. The fourth ventricle was not distended.

On section of the cerebrum a large median tumour was found immediately under the corpus callosum. The growth was dark greyish-red in colour and very soft and vascular. It had invaded almost the whole of the under surface of the corpus callosum, from the anterior to the posterior part, and from side to side. The upper surface of the corpus callosum appeared normal. On section the fibres of the corpus callosum were seen to form simply a thin layer of white matter just above the tumour. The left lateral ventricle was dilated and contained a considerable amount of serous fluid, but the tumour did not invade the left ventricle. The right lateral ventricle was filled with the tumour growth from the anterior to the posterior part, but the outer wall of the ventricle was not invaded by the growth. The white matter of the cerebral hemispheres, the basal ganglia, and the cerebral cortex were not invaded by the tumour. The third ventricle was dilated and contained serous fluid.

The exact starting point of the growth could not be determined, but it appeared to have commenced in the middle line just under the corpus callosum, probably in the velum interpositum. The tumour affected all the structures in the middle line between the corpus callosum and the basal ganglia; it invaded the lower layer of fibres of the corpus callosum, and it filled the right lateral ventricle but did not



Vertical transverse section of brain through anterior part of lateral ventricles. LV=left ventricle. Tumour, deep black.

invade the left ventricle. (See figure.) The tumour was a vascular, round-celled sarcoma.

The diagnosis of tumours in the region of the corpus callosum and lateral ventricles is very difficult and often impossible, and I do not propose to analyse the records previously published in medical literature. I wish simply to report the facts of my case.

The chief clinical features of the case were the following. 1. The fine tremor of the lips, tongue, facial muscles, and of the hands and arms; the tremulous speech and mental impairment; symptoms suggesting general paralysis, but differing in the points already mentioned. 2. The absence of headache and vomiting until the termination of the disease (last two weeks of life). 3. The marked double optic neuritis. 4. The well-marked Babinski and Oppenheim reflexes on *both* sides, without ankle clonus or definite paresis of the limbs.

The presence of the well-marked Babinski and Oppenheim reflexes on *both* sides suggested a median intracranial lesion, and did rouse at one time the suspicion of tumour of the corpus callosum; but it was not felt that this localisation could be made with certainty from the symptoms. I think it probable that in cases of intracranial tumour the presence of *bilateral* Bakinski or Oppenheim reflexes, without ankle clonus or paresis of the limbs, will be found to be a useful indication of a median position of the tumour growth.

The accompanying figure represents a vertical transverse section of the cerebrum through the anterior part of the lateral ventricles and corpus callosum. In sections made posteriorly the growth was much larger.

Manchester.

THE Philosophic Faculty of the University of Marburg has conferred the degree of Doctor (*honoris causâ*) upon Mr. Ernst Leitz of Wetzlar, principal of the firm of E. Leitz, manufacturers of microscopes, microtomes, and photographic lenses.

# SUBLUXATION OF THE KNEE.

BY J. J. W. EVANS, F.R.C.S. ENG.,
URGICAL REGISTRAR AT WESTMINSTER HOSPITAL.

I DESIRE to report two cases of the above injury partly to discuss some points in the established treatment which seem to me illogical, and partly to record an interesting complication of treatment. I shall deal with that form of subluxation of the knee which is associated with injury to the semilunar inter-articular fibro-cartilages. The most common lesion is a detachment of the anterior end of the internal semilunar cartilage. The external cartilage is very rarely injured, and when injury occurs it is usually a transverse splitting of the cartilage. The damage is almost always done by a sudden rotatory movement with the joint in the flexed position.

In studying this condition it will be well to notice certain points in connexion with the structural peculiarities and movements of the joint which are of vast importance in controlling the nature of the injury and clinical signs produced. The main strength of the joint lies, not in its capsule, but in the reinforcement of the capsule by the tendons of muscles surrounding it—e.g., the semimembranosus and popliteus; also in the site and disposition of the crucial ligaments, which cross one another like the limbs of the letter x. This arrangement of the crucial ligaments allows of gliding rotatory movement of the femoral condyles upon the tibial articular surfaces. This movement of the external condyle is, however, limited by the small size and circular disposition of the external semilunar cartilage and also by the insertion of the popliteus tendon into the external condyle, together with the fact that the axis of rotation passes through the external condyle. Thus, the range of rotatory movement of the internal condyle is greater than that of the external.

The semilunar cartilages are connected with the tibia in the following manner. Both cartilages are bound to the tibia at their peripheral surfaces by the coronary ligaments. The external semilunar cartilage is attached by its cornua to the rough surfaces immediately in front of and behind the spine of the tibia, the posterior cornu being strengthened by a band from the posterior crucial ligament. The internal cartilage has its cornua much more widely separated; the posterior horn is attached to the tibia just behind that of the external cartilage and is to some extent held in position by the posterior crucial ligament; the anterior horn is weakly attached to the front of the upper surface of the tibia and is connected to the external semilunar cartilage by a band called the transverse ligament.

Seeing the greater mobility of the internal femoral condyle and the weak attachment of the anterior limb of the internal semilunar cartilage, one can easily explain the great frequency with which the said limb is injured. Situated beneath the fold of synovial membrane which sweeps from the surface of the joint capsule backwards to the crucial ligaments is a pad of fat the function of which is to sink backwards and fill the space formed between the articular surfaces during flexion. Now the lateral extensions of this synovial fold are attached to the anterior extremities of the semilunar cartilages, so that when the anterior part of the internal cartilage is detached from the bone it sinks between the opposing bony surfaces during flexion of the joint, and becomes nipped between them during extension. The above explains the locking which so frequently occurs during this accident.

The movements occurring at the knee are two: (1) The hinge action of flexion and extension; and (2) a combination of rotation and gliding, most marked in the internal subdivision of the joint and occurring only during flexion of the articulation. The "screw-home" action of the joint consists of external rotation of the tibia upon the femur as the first part of the action of flexion, and internal rotation of the tibia as the last part of the act of extension. This enables one to stand upright without using the thigh muscles. During full extension there is no lateral movement in the normal knee-joint; but when the semilunar cartilage is injured lateral movement can be obtained towards the injured side due to removal of the lateral support of the structure.

The clinical signs of cartilage displacement are: (*a*) Pain associated with locking of the joint due to nipping of the displaced cartilage between the femur and tibia when extension is attempted. The pain, which is severe, is due to stretching of the ligaments. (*b*) Synovial effusion, often blood-stained in the first attack, follows the locking and is due to traumatic synovitis. (*c*) In some cases the cartilage may be felt displaced forwards to the inner side of the patella; more frequently a tender spot marks the position of the injury. (*d*) Lateral mobility is possible with the joint in the position of full extension. (*e*) There are usually some muscular wasting and flaccidity of the thigh on the affected side.

The conservative treatment of this injury consists in fixation of the joint in the extended position for a period of about six weeks after replacing the cartilage; this is followed by application of an apparatus of one of two kinds.

1. One consists of lateral irons allowing of hinge action at the level of the joint and fixed to the limb above and below by bands encircling the part. This is applied in the hope of preventing the rotatory movements which cause the injury and displacement of the cartilage. The lower band fixes well upon the leg below the tubercle of the tibia. The upper band is applied to the thigh about three inches above the level of the joint, at which site the femoral shaft is practically cylindrical and has a thick covering of soft structures which, together with the fact that the skin is freely moveable upon the subjacent fatty tissues, I am assured render all hope of preventing rotatory movements (which have been shown to be normal and necessary) absurd.

The following are the measurements of soft structures covering the femoral shaft three inches above the joint in six cases taken consecutively on the post-mortem table:—

| Sex. | Anteriorly. | Internally. | Externally. | Posteriorly. |
|---|---|---|---|---|
| F. | ¾ inch. | 1 inch. | 1 inch. | 1½ inch. |
| F. | ⅞ ,, | 1¾ ,, | 1¾ ,, | 2¾ ,, |
| M. | 1 ,, | 1¼ ,, | ⅝ ,, | 2¼ ,, |
| M. | 1 ,, | ⅞ ,, | ⅝ ,, | 2¼ ,, |
| M. | ⅝ ,, | ¾ ,, | ⅞ ,, | 1¾ ,, |
| F. | ⅝ ,, | ⅝ ,, | ¾ ,, | 1⅜ ,, |

2. The second apparatus is a truss or clip arranged to keep pressure over the site of the anterior end of the internal semilunar cartilage; as I have shown, locking occurs when the cartilage is dragged in by the synovial membrane between the opposed articular surfaces, so that I fail to see what can be gained by applying an apparatus, the aim and object of which are apparently to displace the cartilage backwards and so ensure frequent attacks.

Treatment is then reduced to: (*a*) Fixation of the joint immediately after the injury for about six weeks in the extended position. (*b*) If the above measure fails there remains only the radical method of excising the injured portion of the cartilage. This course is open to the danger of septic infection at the operation; and this is a very real danger, as the synovial membrane of the knee is so complicated, and the joint is usually in the state of traumatic synovitis at the time of operation. These perils should make one especially careful of one's asepsis.

CASE 1.—A woman, aged 23 years. Three years before admission to the hospital the patient was on a step-ladder and in turning to come down the knee became locked; this was followed by swelling. She had a similar attack six weeks before admission. On examination the internal cartilage could be felt displaced forwards and was tender. At the operation the anterior part of the internal semilunar cartilage was found to be torn from its attachment and was removed. Reactionary hæmorrhage occurred into the joint, and on the eighth day the joint was reopened and drained. The patient was discharged from hospital six weeks after operation with good movement. I would account for the small number of attacks in this case by the fact of the cartilage being displaced forwards. The hæmarthrosis which occurred appears not to be a very dangerous complication if promptly treated by irrigation.

CASE 2.—A man, aged 42 years. Five years before admission whilst walking he slipped on a piece of orange-peel and fell; on attempting to rise he found that his right knee was acutely painful and fixed in the semiflexed position. On manipulation "something clicked in the joint," and he was immediately able to use it. The joint remained swollen and slightly painful for ten days. Since that time the patient had had 60 or 70 attacks similar to the first. On examination the muscles around the joint were slightly wasted, and there was a small amount of fluid in the joint; no displaced cartilage could be felt, and there was marked lateral movement in extension. At the operation the internal cartilage was found to be split and detached anteriorly; it was removed. The patient was discharged with perfect movement on the eighteenth day.

I am indebted to the kindness of Mr. W. G. Spencer and Mr. J. M G. Swainson for permission to publish these cases.

Westminster Hospital.

# ATONIC DILATATION OF THE STOMACH.

BY PERCY A. MITCHELL, M.B., CH.B.,
CLINICAL ASSISTANT MEDICAL OUT-PATIENTS, MIDDLESEX HOSPITAL.

THE following clinical work, commenced six years ago and embodying a new method of treatment, has yielded results which, I believe, will prove of interest to the profession.

Atonic dilatation is a condition of the stomach in which there are enfeeblement of its muscular coats and impairment or loss of its motor power, with great enlargement of the organ.

1. *Etiology.*—The most common cause is over-feeding, either a persistent overloading of the stomach, constantly overtaxing its capacity, or the taking of food too frequently, so that a fresh meal is introduced into the stomach before the previous one has had time to leave it. Insufficient mastication and the bolting of lumps of food are also causes, the pylorus closing to prevent the passage of lumps out of the stomach.

2. *Pyloric spasm of reflex origin.*—Under this heading are included the cases in which the primary cause is found not to be located in the stomach, and the atonic condition has yielded to the treatment only after this cause has been eliminated. It should be noted, however, that once atonic dilatation has become completely established, the removal of the primary cause is not always followed by the restoration of the lost motor power of the stomach without special treatment directed to that organ.

(*a*) Appendicitis. Even in the mildest attacks this may produce pyloric spasm, retention, and impairment of the motor power; and, in fact, it is frequently a history of "dyspepsia" extending over a long period that leads to the discovery of the disease in the appendix.

(*b*) Renal calculi, uterine and ovarian irritation (the frequent association of gastric stasis with erosion of the os uteri may be pointed out), and gall-stones may all produce reflex pyloric spasm, as also phimosis in children.

3. Overwork, worry, irregular hours, lack of exercise, and gastric catarrh from the eating of unsuitable or improperly prepared food, are frequent causes.

### *Course of the Disease.*

The disease usually follows a well-defined course; and the sequence of events, although each stage merges gradually into the other, may for convenience of description be divided into the following stages: (1) Gastric stasis; (2) chronic distension; (3) muco-gastritis; and (4) atonic dilatation.

1. *Stasis* is a retention in the stomach of the products of digestion for an abnormal length of time. It is characterised by a feeling of discomfort, heart-burn, acid eructations, and flatulence. By the method of auscultatory percussion which is described later, and by which greatly increased accuracy can be obtained, the stomach is found to be slightly distended, and a splash can be heard. If six hours after a meal the stomach is distended and a splash obtained, it can be said that there is a state of gastric stasis.

The delay in the emptying of the stomach contents into the duodenum leads to acid fermentation of the retained material, with the evolution of considerable quantities of gas, and this being often repeated a state of chronic distension is reached.

2. *Chronic distension* is a condition in which the stomach is found always distended; temporary distension occurs even in the earliest state of stasis. A sharp line of distinction must be drawn between chronic distension and dilatation. In distension there is an enlargement of the stomach by fluid and gas, but when completely emptied the organ returns to its normal size. In dilatation, even when completely emptied, the stomach does not return to its normal size.

The symptoms of chronic distension are those of stasis, but greatly increased in severity; there are heart-burn, very acid eructations, nausea, great flatulence, palpitation of the heart, and considerable pain in the epigastrium, relieved by pressure or the passage of the gas out of the stomach.

The stomach resonance is greatly increased, extending high up in the axillary line and as far down as the umbilicus. It can be taken as a very useful rule that, when the resonance is greatly increased in an upward direction without a very great increase in a downward direction, the condition is one of distension rather than dilatation; whereas if the signs all point to the stomach being very low in the abdomen, and if in the recumbent attitude the resonance extends far below the umbilicus, it is probably a case of dilatation rather than distension. In chronic distension a distinct splash can always be obtained.

The disease may now follow one of two lines: the over-distension may produce an atonic condition of the muscular coats and dilatation become established, or this last stage may be reached after the stage of muco-gastritis. It is important to realise that atonic dilatation may become established, and the motor power of the stomach enfeebled or lost, without any acute symptoms ever having been felt by the patient, the history of "dyspepsia" extending over a long period being all that can be elicited.

3. *Muco-gastritis* is an inflammation of the mucous coat of the stomach, the result of chronic irritation by the highly acid products of fermentation in fluid retained in the stomach. The acids produced are butyric, lactic, and acetic.

The pathology of this condition is interesting, in that it has a great deal to do with the subsequent history of the case. The mucous membrane is inflamed, and the summits of the folds show minute excoriations or pin-head superficial ulcers; these are scattered about in great numbers, particularly in the pyloric antrum and on the gastric side of the pylorus itself. Several of these little ulcers may coalesce and produce a large superficial ulcer called a "gastric erosion." This does not extend below the mucous coat, having the submucous coat as its floor, and it is thus distinguished from the real gastric ulcer, which involves all the coats of the stomach.

In a more chronic condition the mucous membrane becomes greatly thickened in patches, particularly close to the pylorus. These thickened areas are denuded of epithelium and look very like granulating surfaces. This condition might be called the "granular erosion" for the sake of distinction. These areas, situated close to the pylorus, may be so prominent as to be an actual obstruction to the passage of fluid from the stomach.

It is a law that ulcerated surfaces do not heal unless kept in a state of physiological rest, and in a moveable contractile organ like the stomach it is particularly difficult to secure this and very essential that the rest should be absolute. Now in the fundus of the stomach at this stage is a highly acid irritating mixture, and as this is forced up to the raw eroded surfaces of the pyloric antrum a spasm is produced, the antrum and pylorus contract, and the fluid is prevented from passing out, only to return to the fundus and undergo still further fermentation. It is clear that an eroded mucous surface, constantly subjected to this irritating fluid and to these spasmodic contractions, gets very little chance to heal. Physiological rest of the stomach can only be secured by ridding it of this irritating mixture and allowing the organ to remain free of all food for a time.

The characteristic signs of this stage are great pain and a localised tender spot in the epigastrium obtained by gentle but deep pressure. Vomiting is not a usual symptom, but in many cases the pain becomes very acute and boring in character towards the early hours of the morning, and this is only relieved by vomiting. During the day-time the taking of food may relieve the pain for a short time, due partly to the alkaline saliva neutralising somewhat the acids in the stomach, and it is interesting to note that the secretion of saliva is often greatly increased in this affection. The gastric mucous membrane also secretes large quantities of a clear, very tenacious, mucus, which forms a layer covering the mucous membrane. It is alkaline when secreted and serves as a protecting layer, preventing the delicate glandular structures from being destroyed by the acid contents of the stomach.

When the whole mucous membrane is in a state of chronic catarrh, there comes a time when no free hydrochloric acid is found in the contents, only butyric, lactic, and acetic acids being present. The pyloric glands do not secrete hydrochloric acid, and as it is the hydrochloric acid that has the power of destroying micro-organisms, swallowed either from septic conditions in the teeth and gums or in the food, the pyloric antrum, with its already eroded and granular patches, is left very vulnerable to attacks of septic germs, which find an entry into the underlying tissues, and may thus produce an actual "gastric ulcer." It is certain that this condition of inflamed mucous membrane with gastric

erosion is more common in patients with septic teeth and gums (pyorrhœa alveolaris).

The tongue is furred, with two brown streaks running parallel to the middle line. In two instances I have seen the tongue absolutely black, as if coated with ink.

There is sometimes hæmorrhage in this condition, and the fæces may be black. Probably the hæmorrhage is mostly of an oozing character from the raw surfaces. It is sufficient, however, frequently to raise the question as to whether the case is one of duodenal ulcer: both conditions have a localised tender spot and melæna, with at the same time an absence of the hæmatemesis and vomiting so characteristic of real gastric ulcer. The following point will frequently succeed in clearing up the diagnosis. Mark on the skin with a blue pencil the exact locality of the tender spot, then proceed to empty the stomach of its contained gas by the method described later, and it will be found that the tender spot is one or two inches or more higher up. This "moveable tender spot" is very characteristic of gastric erosion, the tender spot of duodenal ulcer being fixed. This difficulty only arises where the tender spot is low and about the middle line. If the spot is high up, close to the sternum, it is unlikely to be a duodenal ulcer.

The bowels are always obstinately constipated, and the patient loses flesh rapidly, looks sallow and ill, and is unable to sleep on account of the boring pain.

4. *Dilatation.*—An enlargement of the stomach varying within wide limits and from day to day, without the organ at any time returning to its normal size. There are two distinct types—hypertrophic and atonic.

Hypertrophic dilatation is an enlargement of the stomach, with great increase in the strength of the muscular coats and motor power. It is the result of an obstruction to the outlet, and is a true compensatory hypertrophy to overcome the obstruction. Eventually, as gastritis is produced by the retained fluids, a state of atony results.

Atonic dilatation has been already defined, the chief point being an enfeebled muscular coat and impairment of the motor power. It is atonic dilatation only that is dealt with in this article, the hypertrophic type coming within the scope of the surgeon.

The symptoms of atonic dilatation are:—1. Great enlargement of the stomach, its upper limit being frequently high up in the axillary line (increased area of stomach resonance), and its lower limit frequently reaching as far as the symphysis pubis. 2. Succussion; the splash can be obtained at any time. 3. Sense of distension and weight, a dragging feeling due to stretching of the peritoneum, which actually assumes the rôle of "suspensory ligaments." 4. Vomiting of large quantities of fluid of an intensely acid character, which is highly irritating to the œsophagus, pharynx, and nasal passages. 5. If there are any of the patches called "granular erosions" there is great tenderness on pressure. 6. These symptoms are liable to frequent exacerbations particularly if there is over-distension with gas, and during these paroxysms the patient may roll on the floor in agony.

Atonic dilatation may be arrived at as a gradual process with only the mild symptoms of gastric stasis, without the stages of muco-gastritis and erosion, and the patient may state that he has never suffered from anything but "indigestion." There is always some degree of inflammation of the mucous membrane. Stasis leads to a disorganisation of the gastric glands. According to the laws of secretion discovered by Pawlow, the glands in a normal stomach secrete juice of a quality and quantity exactly required for the digestion of the articles of food introduced into the stomach. Now it is obvious that if, in a stomach already containing the products of digestion plus the products of acid fermentation, there is added still a further supply of food, the gastric glands are thrown out of order. The condition in a dilated stomach, with the contents retained for, it may be, days, and the mucous membrane covered with a layer of tenacious mucus, is as far removed from normal as can be imagined; nor is it to be improved by the addition of drugs and chemicals unless some outlet can be found for the products of their action.

Obstinate constipation is an almost constant accompaniment of the condition in all its stages, from the early stasis to the advanced dilatation, and in its late stages the disease gives rise to all the general constitutional conditions associated with toxic absorption from the gastro-intestinal canal. The author is impressed by the fact that these auto-intoxications are far more frequently gastric in origin than intestinal.

*Treatment.*

This brief sketch of the origin and development of atonic dilatation will serve to make clear the various points in the method of treatment now to be described.

The usual treatment adopted in these cases is diet, alkalies, antiseptics and antiferments (carbolic acid, creasote, &c.), and in later stages lavage of the stomach with warm antiseptic fluids by means of the stomach tube. To the tube there are great objections, and in many cases it is impossible to use it. Moreover, although it frees the stomach of its contents and palliates the condition it does nothing to restore the impaired motor function, nor to re-educate the stomach to work automatically. Gastro-enterostomy gives only partial relief, for in these cases there is no actual obstruction at the pylorus, and consequently the stomach very soon becomes dilated again. The radical cure is to restore the motor function of the stomach and to re-educate it to perform its work automatically as it does under normal conditions.

The instrument essential for the carrying out of the treatment is a modification of the phonendoscope. It is a large, fairly heavy instrument (not less than 8 ounces) called Bazzi et Bianchi's, and when placed on the abdomen (the patient recumbent) leaves both hands of the operator free.

*Auscultatory percussion.*—Let the patient lie flat on his back, with the head well down, and place the phonendoscope on the epigastrium, where its weight holds it in position; introduce the two ear-pieces into the ears and proceed to percuss out the stomach, liver, colon, intestines, &c. It will be found that by this method the organ can be mapped out with the greatest accuracy, and less difficulty will be experienced in distinguishing the stomach from a dilated colon or small intestine. Without the instrument it is often impossible to differentiate a dilated colon from the stomach.

The slightest degree of splash, inaudible without the instrument, can now be detected. Grasp the patient firmly by both hands, steady the instrument with the tips of the thumbs, and sharply shake. The splash is quite clear. Another method is, with the instrument in the same position, with the right hand sharply press under the margin of the ribs when a splash is easily obtained. By means of this instrument certain definite sounds can be heard, and it is essential that the physician should train himself to differentiate these and learn their significance:—"Pistol-shot sound": small successive quantities of gas passing through the pylorus. "Explosion sound": large quantities of gas passing through the pylorus. "Sizzling sound": small quantities of fluid passing through the pylorus. "Gushing sound": larger quantities of fluid passing the pylorus. "Debacle": a long-continued rush of fluid occurring towards the end of the treatment, when the stomach completely empties itself into the duodenum. "Waves": (*a*) A low "crunching sound" resembling that made by a man walking on frozen snow, due probably to the churning movements of the antrum. (*b*) A soft "sighing sound," which is only got in an empty stomach across which peristaltic waves are passing. These are not obtained except at the very end of a treatment.

The point on which the whole treatment turns is the discovery of a series of superficial skin areas, the gentle stimulation of which causes contraction of the distended stomach, the opening of the pylorus, and consequent emptying of the contents into the duodenum. It is a pure reflex action. The areas lie along the margin of the ribs, commencing at the tip of the tenth costal cartilage on the left side, ascending to the tip of the sternum and down the costal margin on the right side.

The manipulation is carried out as follows. With the patient flat on his back, place the phonendoscope on the right of the umbilicus and seat yourself on his right side facing his head. Place your right hand on the patient's abdomen with the tips of the fingers at the costal margin, find the tip of the tenth rib, and with the tips of the first, second, and third fingers very gently glide, with a trembling motion, over the skin. A hard tap produces a spasm of the pylorus, and all attempts to empty the stomach are futile for some time. It is the delicate, light touch which is efficacious. After a few seconds or minutes (it varies), action will be heard beginning in the stomach. The first to

leave is always gas; consequently "pistol-shot" or "explosion sounds," according to the quantity escaping at one time, will be heard. Cease the stimulation until that contraction has stopped, then proceed again in the same manner, and all the gas will thus be driven out. Then quite different sounds can be heard: a low, muttering, crunching sound begins; it increases in intensity as it approaches the pylorus, and, this opening, a sizzling or rushing sound of fluid is heard. These waves succeed one another until the stomach is quite empty, and when there is nothing more left the soft blowing sighing sound can be heard as wave after wave travels across the empty stomach.

These sounds are greatly modified by the various conditions in the diseased stomach. In a simple case of gastric stasis, without inflammation or erosion, the above sequence of events can be obtained fairly easily about six hours after a meal. In "distension" the sound of the escaping gas is one of the most remarkable phenomena of auscultation, and is followed by rush succeeding rush of fluid, and "debacle" is frequently obtained.

In gastritis with excoriation or erosion the gas escapes fairly well, but the sound as the highly acid fluid reaches the raw spot in the mucous membrane is quite characteristic. The wave commences with the low crunching sound and works up to the point where you momentarily expect to hear the rush of fluid, when it suddenly stops short. There are two elements that cause this sudden stoppage of the wave. A peristaltic wave cannot pass over an eroded area. This is what we find in other parts of the body; a small erosion in the knee causes the joint to be held quite rigid by the muscles, and the same protective mechanism would appear to apply in the stomach; the muscular coats hold rigid where the mucous membrane is eroded. The second element is the spasmodic contraction brought about by the highly acid nature of the fluid.

In "atonic dilatation" it is more difficult and takes longer to start the contractions, but once started they continue very well. There is always in this condition a great deal of gas in the stomach, and before the fluid can pass the pylorus this gas must be expelled. Owing to the weakness of the muscular coats there is very little strength in the contraction, and very frequently the sound heard is a characteristic one; it suggests a "ball-valve," the accumulation of gas in the pyloric antrum moving up to the pylorus, but not escaping, and making a curious metallic snap as it is forced against the closed pylorus. When, as is always the case after a little time, the gas escapes through the pylorus, it does so with a very loud report, and is followed by a rush of fluid.

In a case of atonic dilatation the treatment for the restoration of the motor function of the stomach is carried out as follows. About five hours after a meal, say at six in the afternoon, the treatment as described above is performed. At the first treatment great patience is required, and usually half an hour or more is necessary to completely empty the stomach. This routine is carried out daily, and at the end of two or three weeks the actual symptoms and signs of dilatation have subsided. It is necessary to continue the daily treatment until at six in the afternoon, after an ordinary luncheon, there is no sign of splash, distension, or retention of food; in other words, the stomach carries out its motor function without any external aid. It is necessary, in order to prevent a relapse, that the treatment be continued daily until the sounds heard are normal—viz., smooth, regular, intermittent waves, and the passage of fluid through the pylorus at every second or third wave. If there is a great deal of gas, or if the waves are broken, irregular, and choppy, then the stomach is still abnormal, although the patient may feel perfectly well.

This disease in all its stages is accompanied by obstinate constipation, and it is one of the most gratifying features of this treatment that at the end of the first week, often earlier, without drugs, the bowels begin to move regularly each morning and continue to do so. I have not yet had a case in which this has not occurred.

Certain points in the treatment are of importance. Once a wave is heard to commence the stimulation should be stopped until that wave has ceased. If further stimulation is commenced before the previous wave is completed a spasm of the pylorus is apt to occur. The treatment should not be commenced until at least four hours have elapsed since a meal, and in the graver cases an even longer time. If a case is a particularly obstinate one, it is better not to try to force it, but to leave the stomach perfectly quiet for an hour, and then recommence the treatment.

The contractions produced by this method are often very powerful, and it is of the utmost importance that this treatment should not be used when a real "gastric ulcer" is present. This ulcer involves all the coats of the stomach, and a very powerful contraction might produce either perforation or violent hæmorrhage.

### *Special Points in Diagnosis.*

It is frequently of the greatest importance to be able to decide whether a dilated stomach is due to an obstruction to the outlet or to an atonic condition of the organ itself. In view of the fact that the operation of gastro-enterostomy is successful in the former condition and so frequently fails in the latter, it would be of great benefit to the surgeon to know if there is an actual stricture of the pylorus, and by the method described the question can often be settled. If, on producing contractions of the stomach, fluid is heard to pass freely, there is certainly no great obstruction to its flow, and by practising this method for a few days, and noting the result, both in the size of the stomach and the passage of its contents, an accurate prognosis might be made as to the benefit, or the reverse, that might be derived from a gastro-enterostomy. If, on the contrary, fluid can only be made to pass the pylorus in irregular little jets, the sound of which is quite characteristic, and if, as occasionally occurs, the contractions produced are so powerful that the contents, unable to pass out by the pylorus, are ejected forcibly through the mouth, then an actual diagnosis of pyloric obstruction could be made. There is, however, a condition of the mucous coat near the pylorus in which the mucous membrane is greatly thickened and the surface eroded (the granular erosion), in which the signs very closely resemble those of an actual stricture; and particularly in this condition, when the acid contents reach these areas, the pylorus contracts spasmodically. A week's observation will usually serve to clear up the difficulty.

### *Cases.*

CASE 1.—A man, aged 29, with history of stomach trouble extending over a period of six years. This patient came to me on Oct. 23rd, 1909. The stomach reached to the symphysis pubis; all the signs of dilatation were present. His weight was 6 st. 9 lb. The urine passed was very scanty in amount, and the bowels were obstinately constipated, often acting only once in the week. He was liable to violent attacks of pain lasting for many hours, in which he would roll on the floor in agony. With the first treatment a considerable amount of gas and fluid passed through the pylorus. It was considered advisable, however, not to attempt to send any more of the stomach contents into the intestine, and nine pints were removed by the stomach tube.

Oct. 24th: Several "debacles"; 5 pints removed by tube. 25th: Great quantity passed by pylorus, 2 pints by tube. Urine increased in amount. 26th: 2 pints by tube; fluid passed freely by pylorus. 27th: Fluid passing freely by pylorus; no result by tube; urine increased. 28th and 29th: Stomach emptied through pylorus; bowels opened naturally without drugs.

Through November, December, and January the treatment was continued daily. The stomach gradually returned to its normal position, the bowels acted every day, the urine was normal in amount, and the patient increased in weight to 9 st. 10 lb. He has remained well without any symptoms since that date, and three weeks ago he reported himself as perfectly well, able to conduct his business, and weighing 10 st. 11 lb.

This patient had had treatment by lavage of the stomach with the tube at many periods during the previous few years with only partial relief, relapses occurring almost immediately.

CASE 2.—This case—a female, aged 35—presents many features of interest on account of the conditions which complicated the dilatation of the stomach. She had been perfectly healthy, accustomed to riding and all outdoor exercises, until four years previously. There was a history of continuous stomach trouble since that date.

On examination the stomach was found to be enormously dilated, reaching to the symphysis pubis. The right kidney was easily felt on palpation, and the uterus was almost presenting at the vulva. A condition of "neurasthenia" was particularly marked: violent crying fits, palpitation of the heart, sleeplessness, migraine, and a feeling described "as if the top of her head was made of cotton wool." The patient was wasted and very weak. Constipation was most obstinate, and a tablespoonful of the liquid extract of cascara sagrada was taken every night with but little result.

She had frequent attacks as follows. Commencing the day following recovery from the previous attack, she would have pain and uneasiness after luncheon, aggravated by dinner, and ending in a restless night. This became worse next day, and by the evening she would have a violent headache and suffer great pain in the abdomen, and vomit. The next day or two would be spent in bed and no food taken. This would relieve her partially, only, however, to be followed by a similar attack as soon as she got up and resumed taking meals.

The treatment was commenced and continued daily for three months uninterruptedly; no stomach tube was employed and all drugs stopped; an enema was administered each morning during the first ten days. The contents of the stomach passed the pylorus at first with considerable difficulty and in small quantities, but daily the stomach assumed a higher position in the abdomen, and at the end of the first month its lower limit was on a level with the umbilicus. After the

tenth day from the commencement of the treatment the bowels acted without an enema and continued regular.

It took nearly a year to complete the cure, and at the end of that time she had gained 2 stones in weight, had no signs or symptoms of stomach trouble, all "nervous" symptoms had disappeared, and the kidney could not only not be felt, but gave none of the symptoms associated with moveable kidney. The uterus also, relieved of the pressure from above, came to occupy a position more near to the normal. She is now, four years after the treatment commenced, quite well, able to ride and play tennis and golf, and shows no signs of a relapse.

CASE 3.—This case is quoted on account of the rapidity with which the stomach regained its normal position and power, and also to illustrate in what an insidious manner such a serious condition can be arrived at. As the patient is a final year medical student he has himself written the history.

"I was up at Cambridge from 1905 to 1908, and periodically used to have to train for the races, which training chiefly consisted in taking hard exercises, running and rowing, and eating enormous meals with the object of sending my weight up. When training I used to eat enormously, whether I was really hungry or not, as I was exceptionally light and fondly imagined I was doing myself good. This did not trouble me particularly until my last term, June, 1908, when I occasionally suffered from severe griping pain in the epigastrium. That was all I complained of at the time, but about six months after, during which I had not been leading a very hygienic life, either as regards food or exercise, I began to feel a sense of distension and discomfort in the epigastrium after meals, which gradually passed off into hunger pains before meals, for which I used to eat, not because I felt hungry, but to allay the pain, which, however, was never at all severe.

This went on for about two years, during which time I used to complain a lot of epigastric discomfort, absence of appetite, wind, occasional feeling of sickness, and general languor. I used to play games, tennis, golf, and Rugby football, but never felt very grand after playing them, and was stopped playing the last named for a short time last winter because I was anæmic and on examination had a hæmic murmur. These, however, cleared off when I was treated.

During these two years my weight, which was never anything very great, dropped about a stone, from 10 st. 6 lb. to 9 st. 6 lb. approximately, but what worried me most was that I sometimes used to feel faint in the wards, and did actually faint on two or three occasions. This liability to faintness and feeling of discomfort and distress in the epigastrium, which it is beyond me to describe, was really what chiefly worried me. Another thing was that I suffered a good deal from sleeplessness; going to bed after midnight, after working, I often lay awake for an hour or so, and on more than one occasion for two or three hours, on account of the epigastric sensations.

I frequently used to try and diagnose my condition, and on examining the abdomen I was often struck with the fact that in pressing out the abdomen, or breathing rapidly in and out, I had a fairly extensive succussion splash, the epigastrium, and even below the umbilicus, feeling like a bag of water swaying about under the fingers."

On examination the stomach was found occupying the whole left side of the abdomen, with a distinct and easily obtained splash; the resonance extended high up in the axillary line. The treatment commenced on Monday, Nov. 7th, and the stomach responded at the end of 10 minutes. A considerable quantity of gas first escaped, and then a succession of "gushes" continued for nearly 20 minutes. This treatment was carried out each day, and by the fourth day the lower level of the stomach was above the umbilicus, and on the Friday, after the treatment was finished, the stomach was about 2 inches below the costal margin. He was taking his meals well, sleeping well, and had no feelings of pain or discomfort in the epigastrium. He played Rugby for his hospital team on the Saturday afternoon.

Since then the condition has been one of uninterrupted improvement, and although the treatment is being continued, there are practically no signs or symptoms to indicate any gastric trouble.

These severe examples are quoted to show the class of case to which this method of treatment is particularly applicable. In less severe conditions, the condition of the stomach yields rapidly to the treatment, and often at the end of two or three weeks all signs of dilatation, distension, tenderness on pressure, pain, and discomfort have disappeared.

Feeling, as the author does, that these conditions of stasis, chronic distension, and dilatation, and often muco-gastritis and erosion, have their origin in a disturbance of the motor function of the stomach rather than in the secretory function, he would venture to suggest that this whole group of conditions could fitly be described by the term "gasterakinesia" (gaster = the stomach; akinesia = without motion).

A great many of the observations upon which this article is based have been carried out in Dr. F. J. Wethered's clinique at Middlesex Hospital, and the author wishes to take this opportunity of acknowledging the generous manner in which Dr. Wethered has placed every facility in his way for carrying out the investigation, and for much valuable advice and counsel.

Harley-street, W.

NATIONAL LEAGUE FOR PHYSICAL EDUCATION AND IMPROVEMENT.—A special Clean Milk Campaign Fund is being raised by this league in order to enable it to circulate free copies of leaflets to farmers, dairymen, and housewives, giving simple, clear, and concise instructions for ensuring the cleanliness of milk. We have already spoken in high praise of the practical character of these leaflets. Contributions to the fund, however small, are invited, and should be sent to the secretary of the league, 4, Tavistock-square, London, W.C.

# POWER OF SPEECH IN CUT-THROAT.

BY DHANJIBHAI H. MEHTA, L.M. & S.,
HOUSE SURGEON, C.D. HOSPITAL, BARODA, INDIA.

IN THE LANCET of Oct. 29th, 1910, p. 1294, mention is made in an annotation of a case under the care of Dr. E. M. Merrins of Wuchang in which he says that his patient with the wound exposed could speak only in a weak whisper but so as to be easily understood, that he could speak much more distinctly with the throat bandaged, and could speak clearly and well with the neck flexed so as to close the wound, thus confirming your own opinion expressed last year (1909) that comprehensible speech is perfectly possible, even though the larynx is divided immediately above the vocal cords.

I am glad to be able to cite a case in support of your view. On Nov. 19th, 1910, a man was admitted to this hospital with a big gash in his throat just below the chin. The larynx was cut clean through, a thin ring-like piece of the thyroid cartilage and the epiglottis being at the upper part of the gash, and the rest of the larynx below. The cords could be seen working with each inspiration. The pharynx also was cut open so that one could see the back of it. The patient, when admitted about two hours after the injury, could speak in a fairly loud voice, even with the wound exposed, though a certain amount of difficulty was experienced in understanding him. With a bandage on, however, he could speak distinctly and loudly. In order to suture the wound we tried to put him under chloroform, applying the mask on his face (in the absence of the mouth-tube of a Junker's inhaler); but as he was breathing almost wholly through the wound we did not succeed for at least 15 minutes, when we removed the mask and placed it over the wound, the patient then promptly going under. It was, however, difficult to keep him anæsthetised for long, as it was not practicable to suture the wound and keep the mask on at the same time. I was therefore compelled to put in the sutures even while the patient was conscious, and was surprised to find that he did not show the least sign of pain all the time I worked on him. Probably there was some anæsthesia, though a colleague was inclined to attribute the state of things to a high degree of fortitude on the part of the patient.

The man when admitted had a slight cough, and the result was that the sutures gave way on Nov. 22nd, though he was fed by nutrient enemata only all the time. As he was getting weaker, however, and as there were three holes in the larynx, one on each side and one in the centre, from which a very foul discharge could be coughed out, feeding through the nose was begun and hot fomentations of iodine terchloride solution (20 minims of Professor T. K. Gujjar's liq. iodi terchloridi fort. to 1 ounce of normal saline) were applied every four hours. Granulations began to spring up, but there was a large quantity of healthy pus each time on the dressing, and as the patient began to complain of pain in the throat and inability to swallow his saliva with ease, hot boric fomentations were substituted from Dec. 1st. Under their effect the laryngeal openings gradually closed up one by one, and to-day (Dec. 18th) there is only a very minute hole left, which will close up in a day or two. As the patient got tired of the feeding through the nose, and as he began to have movements of the bowels soon after he was fed, he was allowed to have peptonised milk by the mouth on Dec. 15th, and from the 16th solid food.

The case, in my opinion, presents the following points of interest: (1) the difficulty of anæsthetising by applying the chloroform mask to the face in the ordinary way, while its application to the wound rendered operative measures very difficult; (2) the possible local anæsthetic action of the chloroform on the larynx, so that sutures could be put in without the patient showing the least sign of pain, even though conscious; (3) the wonderful way in which the wound granulated, notwithstanding the fact that there was a foul discharge from the openings in the larynx which engendered a fear that the patient might succumb to septic pneumonia; and (4) the loud voice and the fairly distinct speech, even with the wound uncovered.

Baroda.

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### A CASE OF COMPLETE INTUSSUSCEPTION OF THE APPENDIX VERMIFORMIS.

BY H. M. COOPER, M.B. LOND.,
LATE HOUSE SURGEON AT ST. GEORGE'S HOSPITAL.

A BOY, aged 10 years, when seen by me was complaining of constant attacks of abdominal pain. After a tea-party the child had had an attack of pain and sickness ten days before. His mother gave him an aperient and he temporarily improved, but the pain recurred eight days later. It came in attacks severe enough to make the child cry. His bowels had been open the day before he was seen by me. He had vomited twice. He looked ill; his tongue was furred, his temperature was 99° F., and his pulse was 90. There was some tenderness in the right iliac fossa, but his abdomen was soft and moved freely. No swelling could be felt; there was no peristalsis. The following day, after an enema, he had constant attacks of pain and sickness. His pulse was 120 and his temperature was 100°. In view of the marked rise in the pulse-rate I sent him to St. George's Hospital for operation.

The patient was admitted under the care of Mr. G. R. Turner. There was some slight general distension of the abdomen. Marked tenderness in the right iliac fossa. No tumour could be felt. The abdomen was opened through the right rectus sheath. No appendix could be seen. On examining the cæcum a mass as big as a man's thumb could be felt in its interior; the relations of the small bowel to the large were normal. On opening the cæcum the appendix in a gangrenous condition was found to be completely intussuscepted. It was cut off after ligature of its base; the parts were so friable that the ligature cut its way right through the gangrenous tissues. There was no bleeding. The opening into the cæcum was closed by a silk Lembert suture; the parts around were packed with gauze and a drainage-tube was introduced. The following day the temperature remained high (102°) and the pulse was rapid. The next day both pulse and temperature dropped, and convalescence, although prolonged by a considerable amount of discharge, was uninterrupted. No slough of any kind was detected in the fæces passed after the operation, though they were carefully examined.

### NOTE ILLUSTRATING THE TREACHEROUSNESS OF APPENDICITIS.

BY ROBERT E. HALAHAN, M.D. DUB.,
HONORARY VISITING SURGEON, BRITISH HOSPITAL, BUENOS AIRES.

THE following case of appendicitis seems interesting on account of the mildness of the symptoms compared to the pathological condition found present at the operation.

A campman, 24 years of age, was taken ill on a Wednesday afternoon with colicky pains in the abdomen. He took a purge, went to bed, and on Thursday got up at daybreak, feeling so well that he cleaned out a water-tank. At midday the pain returned and became so severe that he again took to his bed. His bowels moved freely, he slept pretty well, and on Friday he felt so much better that he decided not to come into town as he had intended to do. His employer, however, advised him to do so, and on Saturday, after a drive of some leagues to the station, he started on the 17 hours' train journey to Buenos Aires. The journey was accomplished without experiencing any marked pain, his bowels moved twice, and on the way he partook of tea, soup, fish, eggs, &c. On Sunday morning he presented himself at the British Hospital, rather ashamed of himself, he felt so well. His temperature on admission was 37·4° C., his pulse was normal, his tongue was clean, and beyond slight pain on pressure over McBurney's point he presented no abnormality. Rectal examination was negative. An ice-bag was applied to the right iliac region.

On Monday morning, when I saw him, his bowels had not moved, the slight tenderness of the day before had practically disappeared, pulse and temperature were normal, and the tongue remained clean. He said he felt quite well. I told him that I thought he had had a very slight attack of appendicitis, but as he lived so far from medical aid I advised operation, to which he agreed. The next day I saw him before the operation. He laughingly told me he was quite well, and felt like getting up and going out. He certainly looked it. Half an hour later I removed an appendix some 6 centimetres long, lying on the outside of the cæcum, with the point directed upwards and inclined towards the posterior parietes. From about 1½ centimetres from the cæcum to its tip the organ removed was quite gangrenous and bathed in evil-smelling foul pus. There was almost no inflammatory reaction to be seen in the surrounding peritoneum, and adhesions were conspicuous by their absence. The appendix was cut off close to the cæcum and the stump touched with pure carbolic acid and buried in the ordinary way. For ten days a drain was kept in at one angle of the wound, the rest of it having been stitched up. Recovery has been uneventful and complete.

The lesson to be learnt from such a case is obvious. When one meets with a case of appendicitis operate on it at once, because symptoms, no matter how trivial, are no guarantee against the most serious pathological conditions being present in the abdomen in this treacherous disease.

Buenos Aires.

### A FATAL CASE OF MYASTHENIA GRAVIS.

BY EDWARD GROUND, B.A., M.D. CANTAB., M.R.C.S. ENG., &C.,
HONORARY SURGEON TO THE WEST KENT GENERAL HOSPITAL.

THE patient was a man aged 51 years, married, one child. He had suffered for some years from occasional attacks of bronchitis. In November, 1908, he developed a cough with some fine crepitation at the right apex, a few tubercle bacilli being found in the sputum. He went to the home sanatorium at Bournemouth and returned in March apparently well. About a month afterwards he began to suffer from loss of appetite and muscular weakness, getting very easily tired after slight exertion, and noticing that occasionally objects looked double, especially when he was out walking. The muscular weakness gradually increased, affecting more particularly the facial muscles and those of the shoulder and back of the neck, so that when he smiled he had a peculiar appearance, the angles of the mouth being drawn upwards but very slightly outwards, and after standing or sitting for a short time he had to support his chin on his hand because his head was inclined to fall forwards. After talking for a little while he became tired and had difficulty in pronouncing his words distinctly, and when at his meals after a few bites his jaw muscles refused to act, so that he was obliged to rest at intervals during the repast; swallowing, too, became difficult after a few attempts. At times he complained of a tight feeling about the epigastrium and a difficulty in drawing a long breath, saying that "the bowels seemed to stop it from going any further." His knee-jerks were normal, as was his temperature except when he had a bronchial cold, but his pulse varied between 90 and 100.

As his condition was gradually getting worse, on Sept. 8th, 1909, I took him to see Dr. Purves Stewart, to whom I am indebted for the following notes taken at the time:—Speech, articulation, discs, pupils, and external ocular movements were normal, but the orbiculares oculorum were weak, the patient being unable to hold the eyes shut against resistance. "Nasal" smile was marked. The masseters were feeble and hardened very imperfectly. The palate and tongue were normal on movements. There was no cutaneous anæsthesia or analgesia. The neck muscles were very weak, the head tending to fall forwards, so that he had to hold it up on one hand, supporting that elbow with the other hand. The muscles of the hands were feeble, but less markedly than the proximal muscles. The diaphragm was very feeble. He could not lift one leg across the other without the help of the hand. The gait was normal, but feeble. No localised muscular atrophy was present. Reflexes: Knee and ankle jerks normal; shoulder jerks not elicited; plantars flexor. The left trapezius was tested for electrical reaction. It acted to faradism

briskly at first, but in a few seconds the muscular spasm faded away, even with a powerful interrupted current.

Injections of soamin were commenced on Sept. 10th and were discontinued on Oct. 10th after 12 injections. On Oct. 11th he caught cold, had a feeble cough, and a bad attack of dyspnœa during the night. He complained very much about this time that he could not talk properly when lying on his back owing to falling of his lower jaw, but he could talk more distinctly when he turned on his side; and when unlacing his boots or leaning forward to remove his socks he had to hold his head with one hand to prevent it from falling forwards. He remained in much the same condition until the end of October, when he thought that he felt a little stronger and had less difficulty in taking his food, but on Nov. 9th he again suffered from what appeared to be a slight attack of bronchitis with a very feeble cough, dyspnœa, and great restlessness, and he died on Nov. 11th from failure of the muscles of respiration.

A complete necropsy was not permitted, but a portion of the right pectoralis major was removed for microscopical examination. Patchy infiltration of lymphoid cells was present, the characteristic lesion in myasthenia gravis.

Soamin, hydraurum, iodide of potassium, mercury, and inhalations of oxygen were tried, but had no effect in arresting the progress of the disease to its fatal termination.

### SURGICAL SECTION.

*Cancer of the Rectum.*

A MEETING of this section, adjourned from Jan. 10th,[1] was held on Jan. 18th, with the President, Mr. RICKMAN J. GODLEE, in the chair.

Mr. A. BOYCE BARROW said that he wished to show how little inconvenience a patient experienced from the existence of a colostomy. He referred to communications from patients upon the subject, notably of one who had been operated upon eight years ago who took very active exercise, bicycling, &c. He spoke of the gradual manner in which he had been brought to adopt the colostomy in association with the operation for cancer of the rectum. He mentioned the case of a patient which illustrated that colostomy was often called for after operation with junction of intestine had been attempted. That case afforded evidence also of the difficulty of deciding upon the wisdom of attempting removal. He contended that colostomy was an important factor in successful removal of disease. It simplified the procedure and it allowed of the operation being more complete. It also rendered the aseptic or antiseptic character of the operation being perfectly conducted, and a patient realising the nature of his disease should be prepared to make a considerable sacrifice of his comforts in order to facilitate its complete removal. The loss did not compare with the loss of an arm or a leg affected with a similar disease. An operation for cancer in any situation of the body must aim at the removal of two conditions: (1) the evident and recognisable disease, and (2) the possible extension of the disease to surrounding and more or less distant parts. That extension of the disease might be unrecognisable. Mr. Barrow contended that any operation which did not embrace the second condition of extension or spread of the disease was behind the times—because it had been so abundantly shown that the great improvement in the results of the operative treatment of cancer depended upon the more complete removal of the lines of extension of the disease. He recommended the abdomino-perineal operation as the most complete method yet practised for the removal of the disease, and associated with colostomy the operation was a decided success. The operation was rather a long one, and one must take means to lessen shock. Mr. Barrow drew attention to hæmorrhage and the degree to which the anæsthetic was given as the most important factor in the production of shock. He said that very little blood need be lost in the abdomino-perineal operation because all the important vessels could be secured before being cut. He also gave instances to show the freedom of a patient from shock after long operation when those two factors were watched. A further recommendation of the method was its aseptic character, thus protecting the patient from the pain and dangers associated with any inflammatory condition. As regards the technique of the operation he placed the patient in the lithotomy position for the perineal part of the operation, and he did not remove any bone, not even the coccyx.

Mr. W. SAMPSON HANDLEY said that the view had been put forward that it was sufficient in rectal cancer to remove the growth as seen by the naked eye, together with an inch margin of the apparently healthy mucosa above and below. That was to say, an operation was performed which would suggest itself by the light of nature to a surgeon entirely unacquainted with the pathology of carcinoma. Years ago a similar operation was habitually done in the case of breast cancer; the growth was excised from the breast, and the axillary glands were left untouched. It was strange to remember that as late as 1887, when Banks advocated the routine removal of the glands in breast cancer before the Harveian Society, only a single speaker supported him. Step by step, as pathological knowledge had increased, the scope of the operation had gradually widened in some directions and restricted itself in others, until the modern operation for breast cancer, described with equal vigour and inaccuracy as "removing all but the ribs and crippling the patient for life," had established itself. And at each step of that progress there had been a marked improvement in results, so that local recurrence in the field of operation was now a rare event, and functional disability was practically absent. In the operative treatment of rectal carcinoma they might anticipate with confidence a similar process of evolution. The necessity of removing a considerable length of bowel was shown, not only by his own researches, but by the clinical results of Mr. Swinford Edwards, which were exactly in accordance with his observations. It had been argued that his observations on the spread of rectal cancer must be incorrect, because recurrence, when it took place, involved only a small area at the site of operation; it was implied that if permeation was so extensive the obvious recurrence must be equally extensive. To that he would reply that he had seen a primary sigmoid growth extending along the wall of the bowel nearly to the splenic flexure. He showed a specimen of rectal cancer with an isolated oval patch of secondary growth extending up the bowel three inches above the upper border of the primary growth. As a rule, however, the obvious recurrence was very local for two reasons, first because permeation was a slow process which only produced naked-eye phenomena after a considerable period. It was only in those regions where permeation had been long present, that was to say in the region close to the primary growth, that naked-eye recurrence was to be expected. Secondly, the area of the obvious recurrence was reduced by shortening of the affected length of bowel owing to contraction of the growth in a longitudinal direction. To remove an adequate length of bowel, to control hæmorrhage at the beginning of the operation, and, above all, for the careful removal with visual aid of the fat and glands of the meso-rectum, the perineal and sacral operations must be replaced by the abdomino-perineal methods. The attempt to preserve the natural anus by bringing down the cut end of the sigmoid led, as continental experience had shown, to a largely increased operation mortality. Moreover, it involved the risk of recurrence in the anal region, a calamity which took place in the last case he had operated upon by the perineal method. For those reasons, speaking generally, he advocated an operation on the lines described last year by Mr. W. E. Miles, and he believed his recent paper would lead to a great advance in the treatment of rectal cancer in this country. Mr. Handley had himself practised a similar operation for two years, and in three cases. All of those were living and had no signs of recurrence. Had the operation been the dangerous adventure depicted by one of his critics, he (Mr. Handley) could hardly believe that fortune would allow him an initial sequence of successes. Goullioud had published a series of 11 cases in women, all of whom recovered. It was necessary to recognise that the radical abdomino-perineal operation was a severe

[1] See THE LANCET, Jan. 14th, 1911, p. 100.

one, and that its mortality was higher in men than in women. In old or feeble patients of either sex, but more especially in men, he should still employ a limited perineal operation if the growth were situated low down, or should content himself with a colotomy. It had been stated in reference to a case of his operated upon by the combined method, that according to his own statement he had done a perfectly useless operation, because on examining the specimen he found evidence of permeation of the bowel as far as the line of section. He was quite ready to admit that he failed to attain the surgical ideal of complete removal, but his operation secured a better approximation to it than the limited operation, and in that way he believed that he minimised, so far as was possible in that particular case, the chance of recurrence. Surgeons often claimed far too much credit for their successes in dealing with cancer. An absolutely clean removal of every cancer cell present in the body was probably a rare event. Freedom from recurrence was common because natural processes of cure destroyed or inhibited the few remaining cancer cells. Those facts explained the not inconsiderable amount of success attainable by very incomplete operations. They in no way justified the abandonment of the surgical ideal of complete removal, for experience had shown, more especially in breast cancer, that the more extensive operations, if guided by pathological knowledge, produced greatly improved results. The ideal might be unattainable, but the struggle to reach it found its full reward. One advantage of the combined method was that they widened the limit of operability and enabled them to aim more often at cure instead of merely at palliation. If the perineal method was applicable only to one case in four of rectal cancer surely it could not be the ultimate resource of surgery. It was the duty of surgeons in dealing with rectal cancer to advance along the lines laid down by pathology so far as they were able without subjecting the patient to undue risk. It was, of course, to be much regretted that a reasonably safe, and at the same time an adequate, operation could only be done at the price of a colostomy opening. But the disability, though real, was not inconsistent with a normal life of work and social intercourse. The methods which aimed at a restoration of the normal function of the anus were only successful in a small percentage of cases. The ideal result of those cases was dearly bought at the cost of many operative fatalities or at the cost of preventable recurrences. Other cases remained with a permanent sacral anus or suffered from incontinence or stricture. If the surgery of rectal cancer was to advance the ideal of restoring anal function must be abandoned as inconsistent with the other and far more important ideal of complete and safe removal of the disease on the lines laid down by pathology. It must, however, be admitted that the pathology of rectal cancer was not yet fully worked out. For some years he had been endeavouring to trace the spread of cancer of the rectum, and until recently without success, owing to the proneness of the carcinoma cells to mucoid degeneration and the consequent difficulty of recognising them in microscopic sections. About two years ago it occurred to him to employ mucicarmine, a specific stain for mucus, and by the aid of that stain he thought he was able to demonstrate the spread of permeation along the mucous lymphatic plexus of the bowel a distance of six inches from the primary growth. He was now able to demonstrate another case showing similar appearances extending to a distance of four inches from the obvious or naked-eye edge of the growth. It rested with his (Mr. Handley's) critics to explain what those appearances were if they were not those of permeation of the mucous lymphatic plexus by cancer cells. He had been unable to find wider permeation in a small series of normal rectums. Though an occasional isolated element might take on the mucicarmine stain, nothing could be seen in the normal bowel in the least comparable to the small groups of sharply defined mucoid cells, irregular in size and shape, which might occur at frequent intervals in the cancerous rectum to a variable distance from the macroscopic edge of the growth in the plane of the mucous lymphatic plexus. Beyond a certain point they ceased to be visible, and that point was, in his opinion, the true microscopic growing edge of a rectal carcinoma within which the surgeon's knife must not willingly intrude.

Mr. F. C. WALLIS said that during the last ten years the surgery of the rectum had made great progress, and this was more particularly the case in other countries. But in this country also in the last few years a much more intelligent interest had been taken in this branch of surgery by practitioners at large, who more and more appreciated what a valuable asset a proper knowledge of this subject was, and what before were looked upon as more or less mysteries were now treated in a rational manner, and thus the relief of pain for the patient was much earlier and of a more practical character. The first essential for good results was early diagnosis, and that could only be obtained by a proper examination being made at the earliest moment the symptoms were complained of instead of the whole thing being shirked as long as possible by both practitioner and patient. This was a grave responsibility which rested with the practitioner, and it behoved those who had the opportunity of early examination to do this as soon and as thoroughly as possible. If this became a routine practice the diagnosis would be made much earlier, and so the results of the operation would be greatly improved. Before deciding if any operation shall be done in cases of rectal carcinoma, one of the most important matters to decide was whether the growth was a fixed one or not. This decision, as a rule, should not be made until the patient had been examined under an anæsthetic, and even then the decision might be of some difficulty, especially if the growth was adherent in front to the bladder, vagina, or uterus. In such cases the growth might be easily pulled down with the viscus to which it was adherent, and thus give a false idea of free mobility. When any such possibility as this occurred during diagnosis it would be obviously wrong, and might also lead to serious disaster if an operation was undertaken either from the perineum or by one of the posterior routes, for when the growth was arrived at it might be found fixed. Also, other parts of the colon and even the small intestines might adhere to the growth. To obviate any such catastrophe, and at the same time to obtain a more thorough knowledge of the growth and its surroundings, an exploratory laparotomy should be made in the mid-line. This was an expediency which he suggested should be made much more use of than was at present the case. The question as to what particular operation should be undertaken was one which was almost acute in its present interest. Any new operation which involved a decided alteration of technique was usually commenced with enthusiasm. The enthusiasts often overdid it and operated on all sorts of cases which were in one way or another unfitted for such a procedure, with the result that the operation was discredited by those whose practical experience, having extended over some years, had settled into a groove in which work might run smoothly but perhaps not so much progress was made, and thus an important advance had often been checked for a considerable time. It was to be sincerely hoped that such would not be the fate of the abdomino-anal operation, which was now so much advocated and was a good one in suitable cases. The technique of this operation had been thoroughly described, and the main details of it could soon be learnt by one or two operations on the cadaver. But this was the least difficult part of the work. The age of the patient, the character and size of the growth, its situation (particularly with regard to its surroundings), the length of the sigmoid loop, the size of the pelvis, and the amount of fat generally in the abdominal cavity, were all matters of clinical importance which it was essential to consider before undertaking this operation. But it could be truly said that most of these points had to be considered in any operation for a high-lying cancer of the rectum. But it was probably for the low-lying carcinomata that this operation would obtain the best results. The involvement of the lymphatics in the submucous plexus in certain cases of cancer of the rectum was admirably demonstrated by Mr. W. Sampson Handley, but whether this was satisfactory to everybody was not certain. Personally, on reading Mr. Handley's views and thinking back over his (Mr. Wallis's) cases he was much impressed with the fact that a certain proportion of such cases which had done extremely well had had a return of the growth in the lower segment after an interval of a year or 18 months. And he (Mr. Wallis) thought that in such a case if the abdomino-anal operation had been performed and the bowel above the growth more freely removed recurrence would not have occurred. It was for such cases that the abdomino-anal method was desirable, and from which probably the best results would be obtained. He could not feel enthusiastic

as to the ultimate fate of the bigger operation which had been performed—namely, excision of the whole of the rectum and possibly a portion of the sigmoid with the establishment of an iliac anus. It could only be very few cases in which such a measure was justifiable, and even amongst the few that were justifiable it would hardly be expected that anything but a high percentage of mortality would obtain. When a rectal carcinoma required such severe measures it was probably far better treated by an ordinary colotomy, and he could give various instances of people who had lived comfortably with a colotomy and a carcinoma for many years, the longest he knew of being ten. With regard to the other operations he was strongly of opinion that the best method of dealing with rectal growths not involving the sphincters was by the sacro-anal method. The great point which he claimed in its favour was that instead of suturing the last two or three inches of the bowel to that which was brought down the anal mucous membrane was excised, and the cut end of the bowel above the growth brought down and stitched to the anus. This was quite a simple matter and all possibilities of a sacral anus forming and the almost certainty of a stricture were done away with. This was a method which he had adopted for the last 12 years and which could be well combined with the abdominal incision when necessary. When the growth involved the sphincters then a wide excision of these muscles was necessary, and this operation could usually be performed through the perineum, especially if a preliminary colostomy had been performed, and, indeed, in such cases this was essential. When a growth was inoperable there was no doubt that great comfort was given to the patient by a colostomy. He (Mr. Wallis) had already mentioned that patients lived in comparative comfort with good general health for many years after this operation had been performed, and he was constrained to mention it again because he remembered a few years ago at the Medical Society of London when a discussion took place on this very subject that grave doubts were cast upon any possible benefit being derived from such a measure. There was no question as to the immense benefit derived especially if the toilet of the colon, which was well known now to most good surgical nurses, was daily carried out and if the growth itself was prevented as much as possible from becoming septic by appropriate treatment. He could not advocate any of the various fancy operations for colostomy, which, in his experience, only caused trouble, and rarely, if ever, possessed those particular virtues which were claimed for the operation. One other point he would suggest in the operation, and that was that the bowel should be opened at the time of the operation. This saved much trouble, was much more comfortable for the patient, and with ordinary care was entirely free from all risks. He had no knowledge of any good effects which had been produced by the action of radium upon a rectal carcinoma.

Mr. P. LOCKHART MUMMERY said that a point which he thought had not received sufficient attention in the discussion was the proportion of cases of cancer of the rectum which were seen in an operable condition. Taking 100 consecutive cases from his own records he found that 8 refused operation, 35 were operable, and 57 inoperable. He said that his definition of an inoperable case was one in which it was not possible, even by an extensive abdomino-perineal operation, to remove the entire growth owing to its involving other important structures which could not be removed or to its having already caused secondary deposits. In addition a few cases were inoperable on account of the age or general condition of the patient. Mr. Harrison Cripps had found only one case in four operable, but that was because he took a much more limited view of what was an operable case. From his (Mr. Mummery's) experience he should say that it took as a rule from six to nine months for a growth to become inoperable from the time well-marked symptoms first appeared. He thought that was a most lamentable condition of things and that a very much larger percentage of cases ought to be seen in the early stages. The cause of this was because patients did not seek advice soon enough and medical men did not make an early examination. It was possible by means of the sigmoidoscope to diagnose any growth below the middle of the pelvic colon in its earliest stage. With regard to the question of what features in a case they should consider as rendering the case inoperable, he believed they should operate whenever there was a reasonable chance of saving the patient. He had seen most brilliant results from what appeared at first to be hopeless cases. Of course, by only operating in favourable cases and refusing to operate in those which were doubtful one could get very good statistical results, but their object was not to pile up good statistics but to do the best they could for the patients who consulted them. And if they could save even a comparatively small percentage of the borderland cases it was worth attempting even though it would almost certainly ruin their statistics. He was one of the first to advocate entire removal of the rectum and cleaning the hollow of the sacrum in June, 1907, and he believed that to be the proper practice, but it was impossible to make hard-and-fast rules, and he did not consider it legitimate surgery at the present time to perform the combined operation in all cases. Clearing the posterior part of the pelvis and removing the rectum were quite sufficient in a certain proportion of cases, and he had patients living as long as eight years after that operation. It was necessary to be guided by the condition present. One of the greatest advantages of the abdomino-perineal operation was that it enabled them to deal successfully with cases otherwise inoperable, but he could not agree with those who maintained that it should be performed in all cases. Local removal of the growth by simply slitting the sphincters or by the posterior route was not in his opinion sufficient, and it had the further great objection that a septic granulating wound was inevitable. By removing the whole rectum and bringing down the sigmoid it was possible to secure primary union in the wound. He had so far had three cases in which complete primary union occurred after removal of the rectum and cleaning out the sacral hollow. Two of those were private patients, and they were out of bed in 11 days and able to walk out of the nursing home in three weeks. The third was a hospital patient, and he also returned home in three weeks. The mortality from resection of the rectum was due to sepsis and peritonitis in over 90 per cent. of cases. The reason that local perineal removal had a low mortality was that sepsis in the wound, though inevitable, was not nearly so serious a matter as in the more extensive operations. If they eliminated sepsis, as they could, the mortality would be as low from the more extensive operations.

Mr. C. H. FAGGE said that his own small experience had been entirely opposed to any of the perineal or sacral operations, and in the last two years he had, except on one occasion, given them up for the abdomino-perineal method; his experience of Kocher's operation (for he agreed with Mr. Waterhouse that sufficient room could be obtained without removal of any part of the sacrum, and that therefore a complete Kraske was unnecessary) had been unfortunate, for all except one of his cases, about ten in number, had died from recurrence after intervals of six months to two years. He thought the first speakers who had spoken in favour of perineal methods alone had rather given their case away by admitting that that method was unsuitable when the growth had extended beyond the bowel wall, for in his experience many patients did not come under observation until the peri-rectal tissues had become involved, as one found in dissecting the excised mass after operation. He believed that the abdomino-perineal route would give some measure of success in even those cases. Some two or three years ago, when becoming dissatisfied with the perineal operation, he met with two cases which finally settled the question as far as he was concerned; in the first, Kocher's operation on a man was followed by death from pneumonia after a few days, and at the necropsy several secondary deposits were found in the liver; the second case was sent to him by one of his medical colleagues, who was much pleased to have detected an early case with the sigmoidoscope. After his last experience he (Mr. Fagge) refused to operate from below without first exploring the abdomen, when he found extensive cancerous peritonitis, and of course no radical operation was done. He had carried out the abdomino-perineal operation six times on patients of his own, and had also on several occasions assisted one of his senior colleagues; in some cases they had operated together, one from the abdomen and the other from the perineum, but had found it unsatisfactory. In one of those six cases he had carried the operation out in two stages, but the bowel, detached and pushed down into the pelvis, had

sloughed, and the patient died from peritonitis; he had seen the same thing happen in the practice of another surgeon. In one of the six patients operated upon by that method it was found after removal of the mass that the rectum was widely infiltrated by tubercle which had originated in the left tube; that was also removed. In the other five microscopical examination showed typical carcinoma; three died shortly after operation, either from shock or peritonitis; and two recovered, but neither had yet passed the three years' limit. As an alternative, when the growth was situated in the upper part of the rectum the abdomino-anal operation as described by Miss Aldrich Blake and as practised by Mayo and others was to be considered, but he was of opinion that for growths in the ampulla—the usual site of rectal neoplasms—it was wise to sacrifice the levator ani and other tissues around the bowel. Unless all the muscles and their nerves could be left strictly intact there was much risk of an incontinent functionless anus after any operation such as the abdomino-anal, which necessitated a perineal dissection, and in his opinion a patient was in those circumstances more comfortable with a colostomy, so that as a routine operation for rectal cancer he preferred the abdomino-perineal method.

Mr. C. GORDON WATSON said that most of the points which he wished to emphasise had been brought out by the previous speakers. He had taken considerable interest in the abdomino-peritoneal method of excision of the rectum during the past two years, and since April, 1909, he had excised the rectum by this method ten times, making a permanent colostomy in eight cases and bringing the bowel down to the anus in two cases; he had also assisted his senior colleagues at similar operations on nine occasions and had taken the opportunity of watching the methods of other surgeons. He believed that the abdomino-peritoneal method with colostomy was the best operation for all low-lying growths which were operable, but that when the mesentery was long enough and the growth was situated above the peritoneal reflexion on to the bladder or vagina the bowel might be brought down through the undamaged sphincters, and he thought that cases which were not suitable for the radical operation should be treated by simple colostomy. He said that the great objection to the radical operation at the present time was the high mortality, which, so far as he had been able to estimate, was about 40 per cent. But he believed that this mortality would soon be reduced to 10 per cent. or less when surgeons were more familiar with the technique. As Mr. Wallis had pointed out, when a new operation became prominent less discrimination was sometimes shown in the selection of cases than at a later period, when surgeons were more familiar with the indications for such an operation. This naturally raised the mortality. When Wertheim's operation for complete extirpation of the uterus by the abdomen was first practised the mortality was equally high, but it had now been reduced to something like 10 per cent. The nature of the operation and the conditions upon which the mortality depended were very similar to those of complete extirpation of the rectum by the combined route. He laid considerable stress on the preliminary preparation of patients for this operation, and he believed that if these preparations were properly carried out the shock was, and should be, a negligible factor. In the cases upon which he had operated he had had no cause for anxiety on the question of shock. The great danger, and the one most difficult to avoid, was sepsis. With regard to the preliminary preparation, he strongly believed in giving a quarter of a grain of morphia one hour before the operation. He had kept all his patients in bed for a week or more before the operation, and had had all carious teeth attended to, and had administered naphthaline tetrachloride internally during that period with a view to diminishing the intestinal flora. He had also in some cases given a b. coli vaccine as a prophylactic before the operation, and in one case an anti-coli serum. The vaccine should not be administered too soon before the operation, because of the danger of operating during a negative phase. Probably the best time to administer the vaccine was five or six days before the operation, and the vaccine used should be preferably made by cultures obtained from the patient's own excreta. He was making further investigations on this point in various cases of intestinal surgery, and he would be glad to know if any Fellows of the society could state their experiences with regard to the value of prophylactic inoculations in such cases. Mr. Mummery emphasised the value of the sigmoidoscope in early diagnosis. In two of his (Mr. Watson's) cases the diagnosis was made solely by means of the sigmoidoscope. Both cases were early carcinomata in the descending loop of the pelvic colon, and could not be felt either per rectum or per abdomen. It had been urged against the operation that it occupied too long a time. He thought that if the details of the operation were carefully worked out beforehand, much time could be saved. In his cases the longest time taken for the complete operation was 1 hour and 40 minutes, and the shortest time 1 hour.

The PRESIDENT said that personally he was becoming convinced that the operation which would be most used was the removal of the rectum and lower part of the sigmoid leaving a permanent colostomy wound.

Mr. SWINFORD EDWARDS, in the course of his reply, explained that he was not wedded entirely to any particular operation, because each case must be judged on its own merits.

Sir FREDERIC S. EVE has kindly furnished us with the following additional note of his remarks made on Jan. 10th. He said that the surgery of cancer was the surgery of the lymphatic system. It was only in recent years that the wide permeation of cancer had been understood. Mr. Handley believed the permeation to extend five inches above and below a rectal growth. Judged by clinical observation and the test of permanent cure, he felt no doubt that operations of the Kraske or perineal type were not sufficiently thorough. Steinthal, taking the statistics of numerous surgeons, came to the conclusion that primary cure was obtained in only one-fourth or one-fifth of the cases operated upon. Gant, taking the work of nine surgeons, found permanent cure in only 15·6 per cent. He looked up Mr. Edwards's article in Burghard's "Operative Surgery" and found that out of 50 cases traced, in only 7 did patients reach the three years' limit, and only 3 of these had exceeded it. Every surgeon was aware that the three years' limit was too short, for plenty of cases recurred after that time. Two of his own cases had recurred after five years. With regard to Miles's statistics, out of 58 cases traced, 54 were known to have had recurrence. Even allowing with Mr. Cripps that some of these cases were unsuitable for operation, it was impossible that any large number of them could have been. These facts showed very clearly that the Kraske or perineal method could not be trusted to give a permanent cure. For many years in clinical teaching he had emphasised the importance of exploring the abdomen in the majority of cases of rectal cancer. The necessity of that was obvious—to ascertain the condition of the glands, of the pelvic peritoneum, the amount of fixation of the upper part of the bowel as well as that of the lower, and finally the condition of the liver. For that reason he formerly advocated the performance of a preliminary colostomy. The advisability of exploring the abdomen was a strong point in favour of the abdomino-perineal method. In recent years his work in that department had been largely influenced by an important article by Rotter on the combined operation, which appeared in Langenbeck's Archives for 1906. Rotter strongly advocated the abdomino-perineal operation with restoration of the continuity of the bowel. The speaker from his own experience believed that the operation which fulfilled the most important conditions—namely, low mortality and a prospect of permanent cure—consisted in performing the abdomino-perineal operation, with the formation of a permanent colostomy. He wished to allude to one or two points in the steps of the operation. After the abdomen had been opened the peritoneum was incised on the outer side of the pelvic colon and sigmoid flexure, and the large intestine, with the peritoneum, was stripped inwards to the middle line; the inferior mesenteric artery was thus exposed with the left ureter. A ligature was placed on the inferior mesenteric artery as high as necessary according to the condition of the glands which lay along it. That completely controlled the blood-supply. The glands and cellular tissue were stripped from the sacrum, and the peri-rectal tissue removed. He agreed with Mr. Miles that in many cases the fat in the ischio-rectal fossæ and the levator ani should be taken away. Since many rectal cases occupied the ampulla it seemed to him impossible to excise sufficient bowel below the growth, unless the anus were sacrificed. He always separated the rectum as low as possible from the abdomen

(as far as the levator ani), and then performed the rest of the operation through a perineal incision, having first closed the peritoneum through the abdomen. The operation of restoring the bowel with the combined abdomino-perineal operation could not be dissociated from the great risk of sloughing of the bowel or of leakage from giving way of the posterior sutures. It was to that sloughing and leakage, together with the more prolonged operation, that the high mortality of the abdomino-perineal operation was due. Among 25 cases published in 1906, Rotter's mortality was 44 per cent.; and in 26 cases published in 1908 Mayo's mortality was 26 per cent. During the last two years he (Sir Frederic Eve) had performed the abdomino-perineal operation, combined with a permanent colostomy, with uniform success. He believed that that operation would present a very low mortality. Though he advocated that operation for the greater number of cases of carcinoma of the rectum—viz., those occupying the ampulla or true rectum—he recognised that when the disease affected only the anal canal and anus it might be right to attack it from the perineum, but the coccyx should be removed, the sacrum cleared, and the groin glands extirpated. If the disease occupied the lower part of the pelvic colon, so that it could not be dealt with entirely abdominally, and involved only quite the upper part of the true rectum, then it was justifiable to attempt the combined operation, with restoration of the bowel. For the restoration of the bowel the invagination method appeared to be least likely to be followed by sloughing. In performing it, there need never be any anxiety as to the possibility of bringing down the colon. Every surgeon had used the incision on the outer side of the sigmoid flexure in order to mobilise it. Mr. Moynihan had suggested that that method could be still further utilised in the combined operation with restoration of the bowel, to mobilise the descending colon by prolonging the incision upwards along the descending colon. In the performance of the combined operation, after closure of the abdominal wound, the restoration of the bowel should be carried out through a perineo-coccygeal incision through which the tumour, with the lower portion of the bowel, should be brought and the junction effected. In this way soiling of the peritoneum was avoided and the perineal wound was very useful for drainage of the pelvis; it also served to keep an observation on the suture line.

## PATHOLOGICAL SECTION.

*Gall-stones and Cancer.—Microscopic Structure of Uric Acid Calculi.—Complement-fixation.—Gas-producing Power of Intestinal Bacteria.—Protozoon-like Bodies in Yellow Fever.*

A MEETING of this section was held on Jan. 17th, Dr. F. W. MOTT, the President, being in the chair.

Dr. J. P. CANDLER (of the Pathological Laboratory of the London County Asylums), in the course of a paper on the Incidence of Gall-stones and of Primary Carcinoma of the Gall-bladder and Biliary Passages in the Insane, said that gall-stones were present in practically 80 to 90 per cent. of all cases dying from primary carcinoma of the gall-bladder; while it had been remarked by Ticehurst and others that gall-stones were rarely found when the biliary passages were affected by growth secondary to that elsewhere. So far as the Claybury statistics showed they confirmed Ticehurst's statement. In primary carcinoma the gall-bladder contained calculi, while cases in which the liver was affected with growth secondary to malignant disease commencing in some other organ showed little or no excess in the incidence of gall-stones. His question was whether the association between gall stones and primary malignant disease of the gall-bladder was so frequent as to justify the opinion that because calculi were found in 90 per cent. of cases of primary carcinoma of the gall-bladder, they were to be looked upon as so potent a factor in the causation of that disease. On the one hand they had statements to show that no less than 20 to 18 per cent. (Hale White and Ticehurst), and 14 to 4 per cent. (Rolleston) of cases of cholelithiasis succumbed to malignant disease of the gall-bladder and ducts. On the other hand, Mayo Robson stated that cancer of the gall-bladder was by no means frequent, and as a primary affection was somewhat rare. These two statements were diametrically opposed. The estimates of Hale White, Ticehurst, and Rolleston were based on hospital statistics. They could not in his (Dr. Candler's) opinion be taken to represent the incidence among the general population. They were based on selected cases, among the general population, who, on account of symptoms arising from the onset of carcinoma, sought hospital advice. The inclusion of those cases would at once increase the incidence of carcinoma of the gall-bladder in relation to gall-stones, and upset the balance of comparison with that of a general population. The incidence of carcinoma in a general hospital could not be taken as indicative of the prevalence of the disease in a general population, nor could the incidence of lung affections among the insane be used to indicate the frequency of those conditions among the sane. If they took Hale White's estimate (viz., that about 20 per cent. of cases of gall-stones ultimately developed primary carcinoma of the gall-bladder and biliary passages) and applied it to the Claybury statistics, then out of the 315 cases there should have been as many as 60 cases of primary malignant disease of those regions, or assuming that 10 per cent. of a general population surviving the age of 20 suffer from gall-stones, then 2 out of every 100 persons should develop primary carcinoma—a supposition which he thought was not justified. It might be suggested that the smaller incidence of primary carcinoma among the insane was due to the fact that their average age at death was lower than the average age at death of a general population surviving the age of 20. If all the cases of gall-stones dying before the age of 60 be eliminated from the Claybury statistics, there still remained 197 cases of gall-stones occurring from the age of 60 upwards. If Hale White's estimate be applied to those cases only, there should have been close on 40 cases of primary carcinoma of the gall-bladder in the Claybury statistics. It was not his intention to discuss the various theories as to how gall-stones acted in producing carcinoma of the gall-bladder, or as to whether gall-stones preceded or were formed after the commencement of malignant disease of that organ; there was probably truth in both suppositions. If, as Mignot believed from experimental researches, a stratified well-formed biliary calculus could be formed in six months, it seemed quite possible that a calculus could be formed as the result of changes set up in the mucous membranes by the onset of carcinoma before operation on, or death, of the patient. From the evidence obtained from the post-mortem statistics at Claybury Asylum he was inclined to the opinion that the incidence of primary carcinoma of the gall-bladder and biliary passages in its relation to gall-stones among the general population was by no means so great as hospital statistics would lead them to believe, and that consequently there was not sufficient justification for assigning to gall-stones so important a rôle in the production of primary malignant disease of the gall-bladder and ducts.

Professor S G. SHATTOCK demonstrated the Microscopic Structure of Uric Acid Calculi. He described the structure as studied by transparent sections made by the methods adopted by pathologists. Some such calculi were cancellous, others compact in structure; that was an obvious macroscopic difference, and it was connected with a difference in the mode of crystallisation. In the cancellous there was a nucleus of cuboidal crystals grouped in irregular trabeculæ, and upon that a series of concentric arcades with interspaces, built up of similar crystals, constituted the "body." In the case of the compact variety the structure was of cones of long crystals set radially to the centre; those might be marked with a series of concentric striæ, and by coarser, less well-defined zones of a finely crystalline material which might almost be named bacilliform and which lay in the lateral interstices between the longer elements. That material was uric acid; for although in marked amount, the most careful chemical analysis of the calculi, in bulk, showed a complete absence of ammonium, sodium, or calcium. A comparison of the different elements with those met with in urinary sediments showed that whilst the cuboidal crystals of the cancellous variety could be matched, elongated forms were rare. The elongation of the crystals, and so the production of the compact forms, was attributed to a highly saturated condition of the urine. The length assumed by crystals in supersaturated solutions was well shown. Miers had put forward the view that it arose from the diminished saturation of the fluid between the sides of adjacent crystals produced *ipso facto*

by the crystallisation, the extremities being free to grow at that end which lay in contact with the supersaturated part of the solution, whilst growth in other directions was retarded. In a supersaturated solution, agitation produced a shower of crystals; the deposition of the finely crystalline uric acid in association with the tufts of long crystals in the calculi was to be explained in the same way. In regard to the nuclei of uric acid (or other) calculi, although shed epithelium and mucus, &c., would always be available, their presence was not essential to start a concretion. In the cancellous kinds the nucleus was a chance aggregation of cuboidal crystals; and such a collection of "rubble" at times formed the very centre of a compact calculus; though in other cases a compact concretion arose as a radially disposed collection of longer forms, such as might arise in a supersaturated fluid at various independent points.

Dr. H. R. DEAN described a series of experiments designed to differentiate the various members of the typhoid and paratyphoid group. The experiments lead to the following conclusions: 1. By the use of the complement-fixation method B. typhosus, paratyphoid A, and paratyphoid B can be easily differentiated from one another. By the use of a suitable dilution of serum it is possible to differentiate paratyphoid B from B. Aertrycke. This series of experiments entirely confirms the classification of Bainbridge. 2. The complement-fixation method affords an extremely delicate and specific means of differentiating between various members of the typhoid and paratyphoid group. 3. Very closely allied organisms can only be differentiated after experiments sufficiently extensive to ensure a knowledge of the dilutions most suitable to the serum and extracts in use. 4. The group reaction and the degree of relationship between members of the group can be demonstrated by the use of various dilutions of an antiserum in the presence of extracts made from homologous and heterologous strains. 5. Under certain circumstances the degree of relationship can be seen during the course of an experiment by observing the time of onset of hæmolysis in the tubes containing the various extracts. 6. The group antibodies can be removed from the serum by a suitably arranged absorption experiment. 7. Excess of bacterial extract has an unfavourable influence on the fixation of complement. 8. The maximal fixation of complement is obtained when antigen and antibody are present in certain definite proportions.

Dr. W. J. PENFOLD read a paper on the Variability in the Gas-forming Power of Intestinal Bacteria. He said that if the B. coli (Escherich) be grown on agar containing a suitable concentration of monochloracetate of soda marked diversity of size was obtained as between the different colonies, some being very large and some being very tiny. If the concentration of the chloracetate was weaker this diversity of size did not occur, but secondary colony formation occurred. By repeated plating on this medium a strain highly resistant to chloracetate was obtained. This resistant strain would be found to have lost the power to produce gas from glucose and lactose and other sugars, but to retain the power to produce gas from alcohols—e.g., mannite, sorbite, dulcite, and glycerine. B. enteritidis (Gaertner) could be varied under the same conditions so that its gas-producing power in the case of different sugars was abolished. This varied organism produced, however, a good yield of gas from alcohols. This B. coli, which after the above treatment had lost the power to produce gas from glucose, retained the power to produce gas from formates. It gave a full acid reaction in glucose-peptone water overnight. This acid reaction occurred quite well in the anaerobic state. Anaerobic growth in glucose-peptone water did not cause the return of the power to form gas from sugars. Various considerations suggested that three ferments were required to ferment glucose in the case of the B. coli: one to produce formate from the glucose, one to split up the formate to carbonic acid and hydrogen, and one to produce acid from glucose other than formic acid. What this acid was would not be known until the chemical products of the new variety were investigated. It was unlikely to be derived by oxidation of the sugar since it occurred in the anaerobic state. The coli-form organisms isolated from urine seemed frequently to be atypical, and work by Herter, Mair, and Wilson, taken into consideration with the above production of artificial varieties, suggested that they might possibly arise by selective processes occurring in the body.

Dr. H. SEIDELIN, who had worked for some years at Yucatan, Mexico, demonstrated certain Protozoon-like Bodies in the Blood Organs of Yellow Fever Cases. The microscopical specimens showed intra-corpuscular and free forms from blood smears taken during life. Some of the intra-corpuscular forms presented a certain likeness to malarial parasites and the ring-shaped collections of chromatin-points seen in a kidney specimen suggested asexual forms undergoing division.

## LARYNGOLOGICAL SECTION.

*Exhibition of Cases and Specimens.*

A MEETING of this section was held on Jan. 6th, Dr. P. WATSON-WILLIAMS, the President, being in the chair.

The following cases, specimens, &c., were shown:—

Mr. CECIL GRAHAM: 1. Pharyngeal Cancer. 2. Chronic Ulcer of the Nasal Septum. There had been four attacks of nose-bleeding, and the galvano-cautery had been applied to a small ulcer on the right side of the septal cartilage. The ulcer was now seen to be triangular in shape, and the septal cartilage was exposed but not perforated.

Mr. A. J. WRIGHT: A woman, aged 34 years, with Swelling of the Arytenoids, Left Ventricular Band, and Inter-arytenoid Space, apparently tubercular, although van Pirquet reaction was twice negative. There was no pyrexia and no improvement with iodines.

Mr. NORMAN PATTERSON: A Denture removed from the Hypopharynx and Upper Part of the Œsophagus. The tooth-plate had disappeared while the patient was swallowing a piece of bread-and-butter. On examination great swelling and congestion were visible in the arytenoid regions. The tooth-plate was not visible, but was shown by a skiagram to be present. Under an anæsthetic the plate was seized and dragged out of the œsophagus, but was caught in the anterior pillar of the fauces, and had to be divided by means of bone forceps before it could be removed.

Mr. ALEXANDER R. TWEEDIE: Specimen of Deformity of the Palate with swelling shown to be pituitary. The patient died from inanition six months after birth. Median hare-lip existed and cleft of the soft palate, through which a soft swelling protruded springing from the roof of the naso-pharynx.—Dr. A. KEITH gave a very interesting demonstration on this specimen, which was a most important one from a developmental point of view, a mass of smooth muscle fibre being found between the two wings of the developing septum nasi. The soft swelling before mentioned seemed to represent pituitary tissue, and Dr. Keith considered that the growing round of bone and raising up of the pituitary body which normally took place in the development had failed in this case.

Dr. G. WILLIAM HILL: A new pattern Expanding Œsophagoscopic Funnel, and an improved Instrument for Examination of the Œsophagus and Stomach, combining direct and indirect vision. The stomach was brilliantly illuminated by the instrument, and small objects detected with great ease.

Mr. W. STUART LOW: 1. Tumour in the Left Parotid Region diagnosed as Cystic Adenoma. The exhibitor strongly advised early removal of tumours, though apparently innocent, in this region. 2. A man, aged 48 years, with a Hard Swelling in Right Submaxillary Region, considered by members to be probably a salivary calculus.

Mr. C. A. PARKER: Case of Laryngeal Tuberculosis.

Dr. W. H. KELSON: Case of Naso-pharyngeal Polypus in a young man. This had recurred after removal two and a half years ago, and Dr. Kelson proposed now to do a more extensive operation for its complete removal.—The PRESIDENT advised division of the septum nasi in this case in order to increase the accessibility of the tumour.

Dr. G. C. CATHCART: Tumour taking Origin behind the Right Tonsil, thought to be a fibroma; also a case of Ulceration of Left Vocal Cord in a man aged 67 years.—Case considered by members to be one of pachydermia, and Dr. W. JOBSON HORNE accounted for the hoarseness by the fact that the vocal cords were not quite on the same plane.

Dr. LIEVEN (Aix-la-Chapelle) demonstrated Instruments for the Intravenous Injection of "606." He stated that the routine treatment for syphilis should still be by mercury, and that relapses after "606" were considerably more frequent than generally supposed. It was most important in the intravenous injection of "606" that the drug should be introduced directly into the cavity of the vein, and should not get into the subcutaneous tissue at all. To make

certain of this blood was first allowed to flow from the vein into the apparatus, and then saline fluid injected before the "606" was introduced; and after the dose had been given saline fluid was again passed into the vein.

Dr. R. H. SCANES SPICER: Case of Malignant Disease of the Pharynx, with skiagram showing irregularities of the vertebræ, supporting his views as to the bearing of chronic irritation on the causation of cancer.

## MEDICAL SOCIETY OF LONDON.

*Exhibition of Cases.*

A MEETING of this society was held on Jan. 23rd with Mr. CHARTERS J. SYMONDS, the President, in the chair, who announced that the Fothergillian gold medal given triennially had been awarded to Dr. F. W. Mott for his researches on the nervous system, especially in connexion with syphilis.

Dr. WILFRED HARRIS showed a case of Syringomyelia with Total Anæsthesia in certain areas. The patient was a man, aged 35 years, who 12 months ago first noticed commencing numbness of the left hand, with difficulty in using the hand. That had steadily progressed ever since. He had had no pain, and had never noticed any unconscious burns or cuts. There was considerable difficulty in using his left hand owing to loss of sensation in the part. There was no muscular atrophy whatever in the hand or limb, and the muscular strength was normal. Well-marked athetosis of the hand was present, especially if the eyes were closed. Hemiatrophy of the tongue was present, the left half being much wasted. There was no weakness of the palate or eye muscles and no nystagmus. There was no weakness of the lower extremities, and the deep reflexes were normal, with flexor plantars. Arthropathy of the right tarsus had been present since early childhood. There was total anæsthesia to touch, pressure, pain, and heat over the left second, third, and fourth cervical areas, including the back of the head and neck from the lower jaw down to the second rib, ending sharply at the middle line. On the right side of the back of the head and neck there was delayed sensation to pain, and a certain degree of analgesia, but tactile sensation there was good. There was no loss of sensation of any form on the right hand or arm, but the loss to pain and heat on the left upper extremity was almost complete, and on the left hand below the wrist there was total anæsthesia to tactile as well as to painful and thermal sensations. Below the navel on the right side of the abdomen at the eleventh dorsal level an area of analgesia commenced, extending down on to the front of the thigh as far as the knee, fading away gradually, involving the eleventh and twelfth dorsal and the first, second, third, and part of the fourth lumbar areas.

Dr. HARRIS also showed a case of Sclerodermia with Hemiatrophy of the Trunk and Left Lower Extremity. The patient was a boy, aged 17 years, who first noticed about five years ago that the skin on the left leg below the knee became pimply and began to break down into ulcers. The leg gradually began to waste, and the condition of the skin had continued ever since to give trouble, being liable to recurrent ulceration. He had never had any pain, but the alteration of the skin on the left lower limb and trunk below the level of the nipples had gradually become more pronounced. No family history of anything similar was obtained. There was marked general atrophy of the muscles of the left leg and thigh, and also of the tissues of the abdominal wall and lower chest as high as just below the nipples (fifth dorsal level). The left half of the body at the level of the navel measured one inch less than the right. Electrical reactions were normal, though diminished. There were marked chronic inflammatory changes and healed superficial ulceration on the skin of the left lower extremity, the changes diminishing in degree above the knee. On the trunk there were definite patches of sclerodermatous change visible on the left side of the front of the lower part of the chest, with numerous small white areas resembling morphœa surrounded by areas of pigmentation. There was no trace of any anæsthesia or analgesia to pain or to heat. The cutaneous changes were visible only on the front of the chest and abdomen, limited sharply to the left side of the middle line, and ceasing just below the level of the nipples. There were no abnormalities in the upper part of the chest, in the left arm, neck, or face.

Dr. F. J. POYNTON showed a case of Mediastinitis, possibly syphilitic in origin. The patient was a man aged 74 years, who was admitted to University College Hospital on Dec. 30th, 1910, complaining of pains over the front of the chest, going through to the back, and conducting down the left arm. Shortness of breath had been present for six months. The pain was gnawing in character and more or less continuous, having no relation to food. Enlarged veins first appeared about three or four years ago on the upper part of the abdomen, and were preceded by a severe pain in that region. Since then they had been gradually increasing in size and distribution, and over the middle of the anterior aspect of the chest had joined into a "caput Medusæ." Dilated tortuous veins extended over the front of the abdomen and chest, also down the left arm—the flow in those over the chest was from above downwards. In both lower limbs there were well-marked varicose veins. Since admission the patient had been treated with potassium iodide. The pain had disappeared for the last 14 days, but more veins had appeared.

Dr. C. W. CHAPMAN and Dr. F. DE HAVILLAND HALL described similar cases.

Dr. HERBERT FRENCH showed a case of Bilateral Paralysis of the Sixth Cranial Nerve with Optic Neuritis following on fractured base of the skull. The patient was a boy, aged 12 years, who presented himself on account of squinting of the eyes associated with severe headaches. It was found that his motor nervous system was natural as regards his body and limbs; his pupils reacted to light and accommodation, and sometimes the axes of the eyes were parallel, though more often there was convergent strabismus, sometimes one eye, sometimes the other appearing to squint the worse. There was complete paralysis of each sixth cranial nerve, the third and fourth nerves being unaffected. Ophthalmoscopic examination showed well-marked optic neuritis in both eyes; the filling up of the physiological cup, the active hyperæmia of the discs and the blurring of their edges being very much more developed in the left eye than in the right. The boy had a scar over the left fronto-temporal region, and upon inquiry it transpired that he had fallen over some banisters in August, 1910, from a height of 30 feet, striking his head in the region of the scar upon a concrete pavement, after which he developed extravasation of blood beneath both conjunctivæ and had almost certainly fractured the base of his skull. It was always possible that in a case of this kind injury to the bones had led to the development of a neoplasm, but in the present instance it seemed much more likely that the fractured base, having been followed by the formation of extensive callus in the region of the basi-sphenoid bone behind the sella turcica, this callus was now either pressing upon or actually including in its substance the long sixth nerves and was also behaving like any other intracranial tumour and producing both severe headache and optic neuritis. As regards the prognosis, the probability was that in the course of months the natural process of moulding of callus would lead to diminution in its bulk and that the optic neuritis would simultaneously subside. Whether or not the sixth cranial nerves would recover would depend upon whether they were actually included in the callus or merely pressed upon. It was possible for a motor nerve to be sufficiently pressed upon to be unable to transmit impulses to the muscles that it supplied without the axis-cylinders of its nerve fibres becoming actually degenerated, in which case, with diminution in the pressure, complete motor power in the affected muscles readily returned; if, on the other hand, the axis-cylinders had degenerated, it was so difficult to maintain the nutrition of the external rectus muscles which could not be efficiently treated by massage or electricity, owing to the difficulty of treating them by the latter methods, that even though regeneration might subsequently occur from the central ends of the motor nerves paralysis of the muscles would persist. This seemed likely to be the case here; in most cases of cranial nerve paralysis from fracture of the skull, however, the prognosis as regards recovery of motor power was good. Two months ago there was cerebral vomiting which had now ceased and the headaches were less severe than they were, so that the callus had presumably become less bulky than it was. It was worthy of special note that in the above case the optic neuritis was very much more marked upon the side upon which the injury to the head occurred.

Dr. FRENCH also showed a case of Aortic Disease with

unusual features. The diagnosis was (?) congenital coarctation. The patient was a girl, aged 10 years, who was found to have a cardio-vascular lesion in the course of routine examination for symptoms other than cardiac. The impulse of the heart was in its normal position—namely, in the fourth left intercostal space in the left nipple line. Percussion detected cardiac impairment of resonance for about an inch out to the left of the nipple line and also for a finger's-breadth to the right edge of the sternum, but not upwards above the third left rib. Although the cardiac impulse was not situated abnormally, it seemed likely that there was an increased transverse diameter of the heart, due very probably to hypertrophy of the left ventricle. This was confirmed by the X ray appearances of the heart. There was no thrill at the cardiac impulse, but over the base there was an extremely well-marked rumbling one, systolic in time, with its maximum intensity not in the second right intercostal space close to the sternum, as would be expected if there was stenosis of the aortic valves, but in the root of the neck behind the clavicular head of the right sterno-mastoid muscle immediately above the inner end of the right clavicle. This rumbling thrill, though felt here with maximum intensity, could also be felt all over both sides of the neck along the course of each carotid artery as high as the angle of the jaw on the right side, not quite so high on the left; also outwards half way to the point of the right shoulder along the course of the right subclavian artery, and similarly to the left along the course of the left subclavian artery, below the left clavicle, as far as the hollow in front of the left glenoid cavity; downwards the thrill, rapidly decreasing in intensity, could be felt close to the right border of the sternum in the first right intercostal space. Corresponding with the thrill there was a rumbling systolic bruit audible all over the thorax, front and back. The point of maximum intensity of this systolic bruit was precisely that of the maximum intensity of the thrill—namely, the root of the neck immediately above the inner end of the right clavicle; it could be heard all along the course of the right subclavian artery, right axillary artery, and right brachial artery, half-way down the right upper arm; along the left carotid artery, up in front of the left ear, and even in the left temporal artery, the bruit here being transmitted higher on the left side than on the right, though in the case of the thrill it was felt higher up on the right than on the left side. The systolic bruit was also quite loud over the left subclavian artery, getting faint in the left axilla, and disappearing in the upper part of the left arm. The child had never had rheumatic fever; she looked sturdy and well-thriven; there was no history of acute rheumatism in the family. There was neither anæmia nor polycythæmia. As regards the diagnosis, it was easy enough to exclude the three commonest varieties of congenital heart disease; with pulmonary stenosis there would almost certainly be cyanosis and clubbing of the fingers, neither of which was present in this case; in addition to which the bruit with pulmonary stenosis was nearly always louder in the second left intercostal space close to the sternum than anywhere else; and although it might be audible over a wide area of the thorax, it was not transmitted into the carotid arteries in the neck or into the arteries in the axillæ and arms. The same argument would serve to exclude perforated septum ventriculorum, the bruit of which, moreover, was always loudest over the lower half of the sternum, particularly at some point between the fourth right and left ribs. The strictly systolic time of the bruit would exclude patent ductus arteriosus, with which the bruit generally ran through systole and diastole with a maximum intensity near the second sound, in addition to which with patent ductus arteriosus the bruit was heard loudest as a rule in the third left intercostal space, near the sternum, and not above the inner end of the right clavicle, as in the present instance. It was conceivable that the patient might be suffering from acquired aortic stenosis, but two arguments against this were, first, that the left ventricle did not appear to be materially enlarged, as it almost certainly would be if there were sufficient stenosis of the aortic valves to produce so marked and widely transmitted a bruit and thrill; and, secondly, with valvular stenosis both the bruit and the thrill would almost certainly have their point of maximum intensity near the inner end of the second right intercostal space, and not above the right clavicle, as in the present instance; nevertheless, that there was stenosis in the aorta seemed clear, and if it was not at the site of the valves it would seem to be in the aorta just beyond the valves. The physical signs did not suggest that the condition was one of ordinary coarctation of the aorta, for this lesion was usually situated beyond the origin of the left subclavian artery, in which case neither thrill nor bruit would be transmitted, one would expect, so far along the right subclavian, right carotid, left carotid, and left subclavian, as was here the case. It was suggested, however, that there might be coarctation of the aorta between the aortic valves and the origin of the innominate artery, and that this was the lesion in the present instance.

Mr. A. E. J. BARKER showed a case illustrating the use of Bier's Bandage for Ununited Fractures. The patient was a man, aged 21 years, who fell off his bicycle in Suffolk on July 24th, 1910, sustaining a compound transverse fracture of the humerus and an external wound of the soft parts. He was dressed by a medical man and advised to go to London. On admission the next day the bone was wired. There were much laceration of the soft parts and periosteum and extravasated blood to a large amount. The fracture ran across the insertion of the deltoid. The wound was almost completely closed. Stitches had to be removed on the second day, as there were much swelling and a rise in temperature. A large quantity of altered blood clot and turbid fluid was let out. After this the temperature fell to normal until the end of the case. Skiagrams showed perfect coaptation. When Mr. Barker returned from his holiday on Sept. 29th there was still a small sinus, and a skiagram showed the ends necrosing. The sinus was split and a small cap of bad bone removed from each end with the wire. A rod of aluminium was placed in the medullary cavity and the ends were pressed together over it. The sinus now began to contract, but there was no sign of union of the bone. On Oct. 18th Bier's bandage was applied for an hour. On Nov. 1st the sinus was soundly healed, but there was still no repair of bone. The elastic bandage was now applied for two hours morning and evening. On Dec. 17th callus was first seen to be forming, and motion between the bones could not be felt as before. By Jan. 1st there was a well-marked mass of callus and the fracture appeared firm. On the 10th the splint was left off. On the 16th the X rays showed good union and perhaps some rarefaction of the upper part of the humerus from disuse. The patient had been encouraged since then to active use of the limb and had had massage applied.—Mr. V. WARREN LOW described similar cases in which he had successfully applied Bier's method.

Mr. P. MAYNARD HEATH showed a case of marked Hypertrophic Arthritis in the Knee of a man.

Dr. F. S. PALMER showed a case of Traumatic Epilepsy.

Dr. J. WALTER CARR showed a case of Epilepsy with Deformity of the Skull.

Dr. J. L. BUNCH showed a case of Rodent Ulcer.

The PRESIDENT showed a case of Multiple Rodent Ulcer and Multiple Epitheliomata of the Face associated with Epithelioma of the Palate.

## SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

### *Yellow Fever.*

A MEETING of this society was held on Jan. 20th, Professor RONALD ROSS being in the chair.

Dr. H. E. DURHAM, continuing the adjourned discussion on Sir Rubert Boyce's paper on Yellow Fever in West Africa,[1] criticised severely the administration of the colonial service. He considered that a mild case of yellow fever was liable to be diagnosed as bilious remittent fever.

Sir PATRICK MANSON said that he understood Sir Rubert Boyce considered the best way to exterminate yellow fever was to destroy the stegomyia mosquito, and in that conclusion the society agreed. The other conclusion of Sir Rubert Boyce was that yellow fever was endemic on the West Coast of Africa, and by endemic he meant that the disease occurred in all the principal towns of West Africa. Sir Patrick Manson agreed that yellow fever occurred year by year in West Africa, but he entirely disagreed with the view that the disease was endemic in West Africa.

After Dr. J. W. W. STEPHENS had spoken, Dr. G. C. WALKER (Sanitary Officer, Gold Coast) pointed out that a

[1] THE LANCET, Nov. 26th, 1910, p. 1552.

great deal of yellow fever could be checked if the loose scrub around the towns in West Africa was kept down, because the scrub held so many stegomyia mosquitoes.

After Dr. W. CARNEGIE BROWN had spoken on the question of bilious remittent fever, Professor RONALD ROSS said that the stegomyia mosquito was found all over Africa and yet it was contended that yellow fever was endemic only on the West Coast.

Sir RUBERT BOYCE, in reply, said that his conclusions were summed up by stating that he had brought forward a mass of evidence which showed the almost continuous occurrence of well-recognised outbreaks of yellow fever for the past 100 years, and an unbroken record for the last 20 years; that the natives of West Africa had shown an almost inappreciable death-rate from the disease, whereas amongst the whites the death-rate had varied from 70 to 100 per cent.; that with the immense black population and the very scanty white population the death-rate amongst the whites had been vastly greater than amongst the natives, and that this extraordinary difference could only be explained by the hypothesis of immunity; that the West Indian negroes were susceptible just like the white newcomers; that the natives could get yellow fever—in other words, that the black had no natural immunity against yellow fever; that the explanation of yellow fever in West Africa was similar to that adopted for other countries by the Brazilian, Cuban, French, German, and American official commissions—namely, that the native or indigenous races were the source of the virus, and that as in malaria they harboured the disease in some form; and that segregation afforded complete protection against yellow fever.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SECTION OF SURGERY.

*The Treatment of Laryngeal Stricture.—The Diagnostic Value of the Luys Segregator.—The Treatment of Chronic Urethritis by Ointments, and a New Instrument Therefor.*

A MEETING of this section was held on Dec. 9th, 1910, Mr. R. H. WOODS, the President, being in the chair.

The PRESIDENT reviewed the history and development of the various methods of treating stricture of the larynx. He showed a patient, aged 5 years, on whom he had performed the operation of laryngostomy nearly 12 months previously for complete cicatricial occlusion of the larynx following diphtheria and laryngo-tracheotomy. The patient's larynx was now quite patent and functioned perfectly during swallowing, but he had not yet decided to close the fistula lest recurrence should take place. He also showed a case of extradural cerebellar abscess and lateral sinus thrombosis, where, in addition to the radical operation on the mastoid, he had tied the internal jugular vein.—Dr. P. DEMPSEY said that the strictures, wherever met with, were not easy to deal with, and laryngeal strictures had always been more or less of a bugbear up to the introduction of laryngostomy. The tubes were unsatisfactory, and in very small strictures it was almost impossible to get any kind of dilating apparatus in from above. He would like to know if the tracheal tube was kept in during the operation, and if the anæsthetic was administered through it. Did Mr. Woods think it would be an advantage to administer a vaccine before such an operation? One of the great dangers was that of sepsis within the first week or so, and possibly a vaccine might prove a preventive. He thought that grafting was a new and good plan. Was one satisfied with the mere incision right down through the strictured part? Did one go through the posterior wall of the cartilage, and, if so, was there any danger of wounding the œsophagus in such cases, and might it not be a good thing to pass a bougie? Did Mr. Woods recommend the leaving of a bridge between the tracheal cannula and the laryngostomy opening? Could he give some idea of the mortality of the operation and the average time it would take an ordinary cases of stenosis from beginning to end? He thought a great many such cases were due to faulty tracheotomies performed in a great hurry and in the wrong position.—Dr. W. MURPHY said that the one thing that struck him was that the surgeon must tell the patient what a wearisome time mechanical dilatation would be, and must himself be provided with infinite patience, but it might be well to try dilatation by mechanical means through the mouth before undertaking a rather serious operation. They wished to know how much of the soft parts inside the larynx ought to be removed. The removal of the false vocal cords had been suggested. In Gluck's operation was there not a danger of having hair growing from the inside of the larynx when the skin of the neck was inturned in closing the laryngostomy wound?—Mr. A. J. BLAYNEY had recently made use of a dose of anti-streptococcic serum. He was much pleased with the results subsequent to the operation, and thought it might be of use in laryngeal cases.—Dr. M. HAYES asked if it would be advisable, in malignant disease of the larynx, to perform such an operation as described so as to form a permanent opening in the larynx for applying irradiation.—Dr. STOKES said he had seen cases where the patient could never do without the tracheotomy tube again. Were these usual cases? How did the vocal cords get on in such cases? It seemed rather drastic to have tin tubes and rubber tubes in one's vocal cords for the best part of a year. Were the strictures usually due to diphtheria, and were they localised in any special part of the larynx?—The PRESIDENT, in reply, said the tracheal tube was kept in, and the child was given chloroform through Junker's inhaler. He had used vaccine in a good number of cases, but he thought it gave uncertain results. In a recent case where he extirpated the larynx of a man he used a vaccine grown from the patient's throat. The operation was not performed for six days after inoculation. The man died from profound sepsis within two days. Within the last three weeks he had excised a cancer, taking away the chief portion of the upper jaw and exposing the base of the skull. He did not depend on any vaccine, but applied a solution of chloride of zinc to the raw surface, and the patient's temperature never rose. As to incision of the cicatrix it was said to be quite enough to cut through the cicatrix, and then depend on the dilatation to cause absorption of the tissue. He did not think that as safe a proceeding as to excise all the cicatricial tissue he could find. It then occurred to him to try the grafting. He did not think a bridge between the tracheotomy and laryngostomy wounds would be possible unless the case was one in which a low tracheotomy had been performed. He believed the mortality was 15 per cent. or 20 per cent. The average time was said to be three to six months, but such a period was much too short for his case. It was 12 months since he had done the child exhibited, and if he took out the tube in six days the larynx would show some slight contraction. They had to wait until all tendency of the cicatricial tissue to contract had disappeared. Unless the false vocal cords were included in the scar they should not be touched—the rule should be to preserve everything that could be preserved. As to hair, in a man he would probably turn the flap up from below the wound; it would be most serious to put growing hairs inside the larynx. The kind of cancer that would likely get any good from X rays would necessarily be a superficial one. He did not think the operation would be much use for the treatment of cancer by radium. In the case shown the vocal cords were involved by the cicatrix and were not visible at all. The child, however, had got good substitutes. Looking at it from below they could not tell it from a perfectly normal larynx. In swallowing not a crumb or drop went the wrong way. He thought the operation showed a very distinct advance in the treatment of such hitherto very unsatisfactory cases.

Mr. R. A. STONEY read a paper on the Value of the Luys Segregator.—Mr. L. G. GUNN had used the instrument and found it difficult to insert; it was often very painful on account of the pressure and the uncomfortable position, and he was not satisfied with the accuracy of its results. It was an excellent instrument with a healthy bladder, but they must be certain that the bladder was healthy, otherwise the results would be falsified. It should be used in conjunction with the cystoscope.—Dr. STOKES had formerly spoken against the instrument, but he had since found that his difficulties were due to his own inexperience.—Mr. STONEY, in reply, agreed with Mr. Gunn as to the uselessness of the instrument in disease of the bladder; but in extensive trouble of the kidney without bladder disease he considered it of very considerable use. It was not to be advocated in opposition to other methods. If too much methylene blue was injected it

would fill the pouch and overflow to the other side and so escape on both sides.

Mr. ANDREW CHARLES, in a paper on the Treatment of Chronic Urethritis by Use of Ointments in the Urethra and Presentation of New Instrument for the application of same, said the ordinary routine of patients injecting aqueous solutions was in many instances fraught with failure, due (1) to inability of the patient to inject effectively; (2) to the fact that the injections had not sufficient time to act; (3) to uncertainty that the solutions were brought into contact with the entire inflamed surface of the urethra; and (4) the glandular orifices might be obstructed with plugs of mucus which did not allow the fluids to penetrate. Oleaginous preparations, according to Janet, adhered to the surface of the urethra, were moulded into the folds, and became incorporated with the mucus and entered into contact with the mucosa, thus permitting a prolonged action of the drug. Lanoline was the best basis as it had the power of taking up aqueous secretions and adhered better to the mucous membrane. Urination evacuated the ointment only in small particles for as long as 36 hours (Finger). The instrument which he suggested for the application of ointments combined mechanical effects, and at the same time applied an ointment effectively to the urethral surface. It possessed the following advantages: (1) simplicity; (2) could be easily cleaned; (3) the urethral surface was completely covered with a large quantity of sterile ointment; (4) the urethra could be massaged on the surface of the instrument, so that the ointment could be forced into the folds of the urethra and into the ducts of the gland; and (5) it acted as a dilator.

---

UNITED SERVICES MEDICAL SOCIETY.—A meeting of this society was held on Jan. 11th at the Royal Army Medical College, Grosvenor-road, S.W., Colonel Sir David Bruce being in the chair.—Captain W. A. Woodside read a paper on the Training of Territorial Medical Units. He described the general method of training of territorial medical units, dwelling on the various difficulties which were encountered and the methods he had adopted for overcoming them. He strongly advocated that after the first year all privates should devote their chief attention to the special duty for which they were detailed in the duty roster, since there was not sufficient time to teach Territorial privates more than one set of duties. On the other hand, non-commissioned officers should have a general knowledge of all duties. It was very necessary that the adjutant should have a competent knowledge of horse management and he gave illustrations of defective arrangements which had resulted from a lack of this knowledge.—Lieutenant-Colonel C. H. Melville read a paper on the Load of the Infantry Soldier. After a preliminary historical survey of the question he showed that the present weight carried in nearly all armies was too great, the more especially as in war it would have to be carried from the start by reservists out of training. He gave details showing that the limit of weight which could be carried without excessive strain was 22 kilogrammes (48½ lb.), while the British soldier, who was quite lightly loaded compared with the soldier of most other armies, carried 58½ lb. Arms, ammunition, and clothing accounted for 35 lb. of this and could not well be reduced. Any reduction could only be made by lowering the weight of accoutrements, great coat, shelter appliances, and "necessaries." A saving of nearly 2½ lb. could be made by making the water-bottle and mess-tin of aluminium and the straps of thinner material. He considered that a great saving could be made by replacing the great coat (6¾ lb.) by a short pea-jacket and a pair of overalls or by making the coat of lighter material. Of the "necessaries" (9 lb.) he would relegate all the cup, cutlery, and small book (total 400 grammes) along with pack (800 grammes) to the second line transport. Clean shirts, towels, soap, and the like were luxuries on service, and expensive luxuries when they were carried at the expense of the fighting efficiency of the soldier.—Surgeon-General Gubbins (Director-General, A.M.S.), Lieutenant-Colonel R. J. S. Simpson, Lieutenant-Colonel J. B. Wilson, Major W. S. Harrison, Major S. Lyle Cummins, Lieutenant-Colonel C. H. Burtchaell, Surgeon-General W. Babtie, Major W. W. O. Beveridge, and Colonel Sir David Bruce took part in the discussion.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 6th, Dr. Phineas S. Abraham, the President, being in the chair.—The President showed a case of Tylosis, also a case of "Mixed" Leprosy in a male, treated with solid $CO_2$ with excellent results.—In reply to Mr. W. McAdam Eccles the President said that leprosy had been treated with "606" but without effect.—Dr. Seymour Taylor showed a case of Typhoid Fever with two relapses, and a case of Pneumothorax.—Dr. Frederick Palmer: A case of Acromegaly in a female aged 58 years, and a case of Rheumatoid Arthritis.—Mr. L. A. Bidwell: A case of Removal of the Posterior Part of the Tongue and Epiglottis for Carcinoma and Ileosigmoidostomy for Artificial Anus.—Mr. McAdam Eccles: A case of Cystic Swellings of the Forehead and in the Thyroid Region in a male aged 65 years. The swelling on the forehead he considered to be a dermoid cyst, the thyroid swelling either a cyst of the thyroid or a tubular dermoid in connexion with the thyro-glossal tract.—Dr. T. Grainger Stewart: A case of Pseudo-bulbar Paralysis of Doubtful Origin, probably a case of Disseminated Sclerosis.—Dr. Arthur Saunders: A case of Tuberculous Adenitis in a girl aged 17 years. The diagnosis lay between lymph-adenoma and tuberculous glands. Examination of a gland removed for the purpose showed it to be tuberculous.—Mr. N. Bishop Harman: A case of Argyrosis of the Conjunctiva produced in a youth, aged 15 years, by the continuous use of protargol drops over several years; and a case of Tuberculous Kerato-iritis in a woman, aged 21 years, in which injections of tuberculin T.R. were made with most beneficial results; also a case of Posterior Polar Cataract with Persistent Hyaloid Vessels in a youth aged 16 years.—Dr. H. J Davis: A case of Empyema of the Antrum in a boy, aged 7 years, with recovery after three operations; Empyema of the Antrum in a man, aged 71 years, in whom the disease had become malignant and the upper jaw had been excised; a case of Recurrent Post-nasal Growth in a youth, aged 17 years, which occurred after three operations (the growth showed large vascular spaces and adenomatous tissue with small round cells, evidently maligant); a case showing the Stapes in the Oval Window in a woman, aged 25 years, on whom a radical mastoid had been performed for otorrhœa (the malleus and incus were removed, the bone was healed in six weeks, and the patient could hear a watch at six inches).—Dr. Kenneth E. Eckenstein, for Dr. J. F. Halls Dally, gave a demonstration of the Sphygmo-oscillometer, an instrument devised by Dr. Pachon of Paris to estimate the blood pressure.

BATH CLINICAL SOCIETY.—A meeting of this society was held on Jan. 6th, Mr. F. Lace, the President, being in the chair.—Dr. A. J. B. Leckie showed a case of Primary Carcinoma of the Liver in a girl aged 6 years (confirmed post mortem). The weight of the liver was 87 ounces.—Mr. Forbes Fraser showed a specimen of an Ovarian Dermoid which had ruptured into the peritoneum. It was attached to the sigmoid flexure by a tubular connexion about one and a half inches in length. The cyst contained foul-smelling fæcal material and vegetable débris, the remains of fruit skins, seeds, orange-pips, &c., being recognised.—Dr. J. Wigmore read notes of two cases of Cæsarean Section and discussed the indications for craniotomy, symphysiotomy, pubiotomy, and Cæsarean section.—Dr. Charles J. Whitby read a paper on the Cancer Problem in the Light of Recent Research. He said that the importance of the cancer problem was enforced by the estimation of Dr. Bashford that the chance of a man over 35 years of age dying from cancer was 1 in 11, and of a woman 1 in 7. He referred to the results of recent researches which seemed to confirm the rationality of treatment by radium and the X-rays, and remarked that it would be premature to apply the results of experimental immunisation to man until such time as definite effects could be produced in animals upon growing vascularised tumours of spontaneous origin as distinguished from recently introduced transplanted growths.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Jan. 17th, Mr. J. Howson Ray, the President, being in the chair.—An address, entitled "The Life-history, Function, and Inflammation of the Appendix," was delivered by Mr. Edred M. Corner. He dealt in the first instance with the physiology of digestion, and detailed the various steps in the process

until the food arrives in the ileo-cæcal region. He laid stress on the fact that in this region of the alimentary tract bacteria were more numerous than at any other part, and discussed their influence in the production of appendicitis. He also drew attention to the part played by foodstuffs. The function of the appendix he dealt with at some length and gave three examples of those cases which he designates as "unconscious and unrecognisable appendicitis."—Dr. H. R. Hutton proposed, and Mr. A. H. Burgess seconded, a vote of thanks, to which Mr. Corner suitably replied.

# Reviews and Notices of Books.

*The World of Life: A Manifestation of Creative Power, Directive Mind, and Ultimate Purpose.* By ALFRED RUSSEL WALLACE, O.M., D.C.L., F.R.S. London: Chapman and Hall, Limited. 1910. Pp. 408. Price 12*s.* 6*d.* net.

THE name of Alfred Russel Wallace is greeted with affection and respect by all directly interested in the progress of science, though many are at absolute variance with him in some of his views. A large reading public doubtless will hasten to make themselves acquainted with the latest message of this veteran in science who just a few days ago completed his eighty-eighth year, and who happily has proved his vigour and force of intellect by being able to "summarise and complete his half-century of thought and work on the Darwinian theory of evolution," now presented in "The World of Life." He, however, goes far beyond Darwin: in fact, he asserts that he purposely undertook a popular and critical examination of those fundamental problems which Darwin expressly excluded, such as the causes of life itself and its more fundamental and mysterious powers—growth and reproduction.

After painting in picturesque language the structure of a bird's feather, the marvellous transformation of the higher insects, and the elaborate wing-scales of Lepidoptera, he tries to show the absolute necessity for an organising and a directive life-principle in order to account for the very possibility of these complex outgrowths, and contends that they necessarily imply a creative power, next a directive mind, and an ultimate purpose. And what is this purpose? The development of Man, the one crowning product of the whole cosmic process of life-development, the only being which can appreciate the hidden forces and motives everywhere at work, and can deduce from them a supreme and over-ruling Mind as their necessary Cause.

The author sees in the remarkable series of events he records in the process of evolution, a creative effort carried on from the beginning of time by an active, creative, conscious spirit with one object, the perfection of man and his spiritual development—as he puts it, "the earth and organic nature having been designed for the development of the human race." The final outcome of all the marvellous cosmic and other changes in geological time and the purpose of the whole series of living beings were in this view to serve the uses and to add to the enjoyments of man—a doctrine which, he admits, is highly distasteful to a large proportion of scientific workers. It is a strange philosophy: all had but one object—the perfecting of man and his spiritual development. Everything on earth and in the sky, the birds of the air, the beasts of the field, the gorgeous insects and the flowers, the minerals in the earth, and the varied products of the vegetable kingdom, "the earth veil" of Ruskin, that omnipresent clothing of the earth's surface produced by the infinitely varied form of vegetation, all were created for man's profit, use, and delectation, and to provide a spiritual school for man. Man is the centre round which turns the whole of this elaborately evolved universe—"this earth, with its infinitude of life and beauty and mystery, and the universe in the midst of which we are placed, with its overwhelming immensities of suns and nebulæ, of light and motion, are firstly for the development of life culminating in man; secondly, as a vast schoolhouse for the higher education of the human race in preparation for the enduring spiritual life to which it is destined."

Leaving aside these ulterior aims, let us glance at the author's text itself, apart from his views on design and on the present as a preparation for a future spiritual state. He sets forth in charming and picturesque language, with a delight and freshness almost boyish in its earnestness, a popular account of the story of evolution, insisting on the co-relation and co-adaptation between the development of the vegetable and animal life through the whole geological period up to the present. Beginning with the question, What is Life? he gives what he calls a tolerably complete definition of life as "that power" which does certain things. With Haeckel's dislike of the dogmas of theologians, he will, however, have none of the Haeckelian philosophy. About one-quarter of the book is taken up with the consideration of species, their numbers, variety, and distribution, much emphasis being placed on variability, on the detailed distribution of plants—British, temperate, and tropical floras—and the wonderful adaptations of some plants to seasons of drought. When considering the distribution of animals, birds and bird-life seem to fascinate the author. He calls birds the most familiar, most beautiful, and the most wonderful of living things, the most specialised of all the higher animals, and, so far as perfection of organised structure is concerned, considers them to hold a higher place than the mammals themselves.

The story of Darwin's conception of "Natural Selection," dependent on heredity, variation, and enormous power of increase of plants and animals, is told with graphic detail and plentiful illustration, including an account of a flight of pigeons 240 miles in length and composed of 2000 millions of these birds, as narrated by Wilson. A similar story is told of the migrations of the lemmings of Norway. "Mutation" and "Mendelism" are ruled out of court as hopelessly inefficient and ludicrously inadequate as substitutes for the Darwinian factors in the world-wide and ever acting process of the preservation and continuous adaptation of all living things. The author waxes eloquent and writes with zest on the theme that the entire animal world depends absolutely on the equally vast and varied vegetable world for its very existence, and that the variety of insect tribes depends on the overwhelming variety of plant species. At last he finds a use for mosquitoes as the food of birds, especially birds that breed in the Arctic regions. A new significance is also found in the colour of nuts. The wonderful co-adaptation of birds and insects leads to a very interesting account of "recognition marks," which are of great importance—perhaps absolutely essential—in the evolution of new species, and in this he gives us a most interesting review and criticism of colour in all its varied relations. In his "Extensions of Darwinism" he has a good word for Weismann's theory of "Germinal Selection"; but here he runs off at a tangent against certain capitalists and legislators, which he calls "a digression." His general conclusion, reiterated as to life-development, is that "beyond all the phenomena of nature and their immediate causes and laws there is 'Mind and Purpose,' and that the ultimate purpose is (so far as we can discern) the development of mankind for an enduring spiritual existence." Our great cities are the "wens," the disease-products of humanity, and until they are abolished there can be no approach to a true or rational civilisation according to the author's thesis that to explain all the phenomena of the whole world

of life we require to postulate the continuous action and guidance of higher intelligences, and that these have probably worked towards a single end, the development of intellectual, moral, and spiritual beings.

Instead of playing the part of critic, we have let the author speak for himself. If we do not wholly agree with his anthropocentric view of creation, and to many it will appear as if the very essence of the idea of evolution is at least greatly minimised thereby, we are none the less charmed with this very readable and delightful book as a popular account of the course of evolution.

---

*Diseases of the Joints and Spine.* By HOWARD MARSH, M.A., M.C. Cantab., F.R.C.S. Eng., Master of Downing College and Professor of Surgery in the University of Cambridge; Consulting Surgeon to St. Bartholomew's Hospital and to the Hospital for Sick Children, Great Ormond-street; Corresponding Member of the Orthopædic Association, New York. Third edition, enlarged and revised by the author and by C. GORDON WATSON, F.R.C.S. Eng., Surgeon to the Metropolitan Hospital; Assistant Surgeon to St. Bartholomew's Hospital and to St. Mark's Hospital for Fistula. With four coloured and eight black and white plates, and over 100 illustrations in the text. London: Cassell and Co., Limited. 1910. Pp. 632. Price 10*s.* 6*d.* net.

SINCE the second edition of this work appeared many advances have taken place in the knowledge and understanding of the various forms of septic arthritis, and in consequence of the application of the X rays to diagnosis and the addition of vaccine therapy to methods of treatment a great deal of new material has accumulated. To make way for the additions and revisions which have been thus called for, without too greatly increasing the size of the volume, some of the case narratives have been omitted. But, as in previous editions, the volume is still a record from the clinical standpoint of the personal experiences of the author, with especial reference to those methods of treatment which in his hands have seemed to be best suited to the various conditions with which he deals.

Within the compass even of 632 pages it is impossible fully to discuss the principles and practice of the treatment of the numerous subjects included, and many excellent methods of treatment are therefore not noticed. The various affections are discussed in the first 15 chapters in a general way, and afterwards in chapters XXIII. to XXX. each joint is considered separately in regard to the affections to which it is most liable. Special chapters on ankylosis, excision of joints for tuberculous disease, interosseous pressure in joint disease, bone-setting, and movements and massage are instructive and interesting, enunciating principles and expressing views of the most approved kind, and full of sound practical suggestion. We would draw attention particularly to the chapter on interosseous pressure in joint disease, where the correct principles of treatment by extension with weight and pulley are laid down in a manner both forcible and convincing. A confusion of terms and ideas has been corrected by the proper and up-to-date classification of the many different pathological states which in the loose phraseology of every-day practice go under such names as rheumatic gout, chronic rheumatic arthritis, &c. The paragraphs on the pathology of some of the secondary forms of arthritis and the chapter on congenital dislocation of the hip-joint cannot be said to be quite up-to-date, and the radiograph of the latter condition on a plate facing page 472 has not been taken with the object of exhibiting the length and direction of the femoral neck, a circumstance which deprives the photograph of some of its practical value. Diseases of the spine are comprised in 74 pages, forming Part II. of the volume, dealing with tuberculous and malignant disease, spondylitis deformans, and neurotic spine. It will therefore be seen that this forms a very small portion of the work.

The book is a record of Professor Howard Marsh's experiences, contains the details of many interesting cases, each with its point of instruction in diagnosis and treatment, and will be found of great practical value to the surgeon.

---

*Manual of Diseases of Women.* By W. E. FOTHERGILL, M.A., B.Sc., M.D. Edin., Assistant Gynæcological Surgeon, Royal Infirmary, and the St. Mary's Hospitals, Manchester; Clinical Lecturer in Obstetrics and Gynæcology in the Victoria University of Manchester. With 144 illustrations in the text. London and Edinburgh: William Green and Sons. 1910. Pp. 433.

THE principles upon which the author has written this manual are well stated by him in the preface. "The life-history of the female reproductive organs is characterised by a period of rest following the time of early development, by a second period of development at the commencement of their functional life, and by a period of retrogression at its close. In addition to these developmental crises the organs are the seat of changes occurring in monthly cycles, and generally also of more extensive changes involved in actual reproduction at varying intervals. The border-line between health and disease is crossed in structures that are undergoing rapid tissue change far more often than in those in which construction, destruction, and reconstruction are more slow and gradual."

In every woman of reproductive age tissue changes occur every month which are so extensive and so rapid that they have no parallel in the whole life-history of the male subject. It is this difference which underlies the distinction between "the diseases of women" and all other branches of medicine. In this book, after a preliminary section dealing with methods of examination and diagnosis, the actual diseases are considered under: Errors of Development, Circulatory Changes, Mechanical Conditions and Injuries, Results of Infection, Progressive Changes, and Retrogressive Changes.

The first section on errors of development is illustrated by some good diagrams. In considering circulatory changes and pelvic congestion resulting therefrom Dr. Fothergill lays stress upon the important fact that, by many authors, chronic venous congestion, hypertrophy, and subinvolution are all classed together with chronic infection under the erroneous and misleading term "endometritis." In the same way in many text-books of gynæcology the grave mistake is made of asserting that the pain in the sides due to chronic pelvic congestion is due to ovaritis, a disease much more often talked about than seen. We need not say that the author strongly condemns such errors as these, leading, as they do, to a misconception of the real condition, and often to meddlesome and harmful treatment. Young girls constantly have ovarian pain, but true ovaritis in such patients is almost unknown.

In the chapter dealing with Mechanical Conditions and Injuries Dr. Fothergill supports the view that the firm attachment of the uterus, vagina, and bladder is effected mainly by the connective tissue sheaths surrounding the vessels, nerves, and lymphatics of the pelvis. This hypothesis appears to us to represent only a part of the truth, and we cannot accept the view that any one portion of the pelvic floor plays the only, or indeed the main, part in supporting the pelvic viscera. We see no difficulty in accepting the more general view that all the component parts of the pelvic floor take their share in anchoring the pelvic viscera in their places, and among those structures the connective tissue sheath of the vessels is no doubt of great importance. Is not the fact that women who have the perineum torn right through practically never have uterine prolapse explained not by the reason the author gives—namely, that rupture of

the perineum and levatores ani is not a cause of prolapse—but rather to the fact that when such extensive tears occur the tissues are not only saved thereby from undue stretching, but also such extensive tears are usually sewn up very carefully? In cases of retroversion and prolapse of the ovaries where operative treatment is necessary the operation is described and advised of drawing the folded round ligaments through an opening in the broad ligaments and suturing them in front of the uterus, thus forming a sling to hold up that organ. Dr. Fothergill states that he has had good results from this procedure.

The arrangement of this manual presents a refreshing novelty, and the manner in which the different diseases are treated of is good and interesting. It contains a large amount of sound teaching in a comparatively small compass and is well worth reading. The classification adopted naturally leads to the inclusion of some conditions under headings in which we would not expect to find them; thus, for example, a vascular caruncle is described in the section on retrogressive changes. It is quite true that one form of caruncle owns this origin, but the common form due to gonorrhœa should be found rather in the chapter on diseases due to infection. The illustrations are good and the index fair.

---

*The Diseases of the Nose, Mouth, Pharynx, and Larynx: A Text-book for Students and Practicians of Medicine.* By Dr. ALFRED BRUCK (Berlin). Edited and translated by F. W. FORBES-ROSS, M.D. Edin., F.R.C.S. Eng., assisted by FRIEDRICH GANS, M.D. Illustrated. London: Rebman, Limited. 1910. Pp. 615. Price 21*s.* net, cloth.

THE translators of Dr. Bruck's text-book state in their preface that they "have endeavoured as much as possible to closely follow the German text; even at the risk of not producing 'classical English' at the expense of the exact 'shade of meaning' or sense which the author originally endeavoured to convey." Unfortunately, it does not seem to have occurred to them that "to closely follow the German text" would actually run them into the very danger they were so anxious to avoid, and that it is possible to translate so literally as to render an author's original "shade of meaning" hopelessly obscure. Indeed, we regret to say that this is actually what has happened. Take the following as an example: "This" (limitation of the olfactory region in the human nose to a small area) "can be taken as a proof of the little delectable fact that the sense of smell in Homo sapiens is on a retrograde movement, or seems to degenerate entirely, in contradistinction to his animal affinities." From this sentence the reader may learn "the little delectable fact" that the translators have performed their task upon the all-too-familiar lines of the fourth form construing the Commentaries of Julius Cæsar.

It says much for Dr. Bruck's writing that many of its merits have survived this treatment. His arrangement of the subject-matter, for example, is clear and systematic, and much of his description retains its pithy and concise character. We commend, among other admirable features, the decision which led the author to incorporate in his book a section upon diseases of the mouth. In this connexion, however, we were unable to discover any allusion to pyorrhœa alveolaris, a disease which plays a not unimportant rôle in the causation of many disorders of the nose and throat.

In his advocacy of caution in regard to the operative treatment of nasal sinus suppuration Dr. Bruck's teaching is in harmony with the most recent movement of rhinological opinion. But we are constrained to add that in many other directions his views and counsels are not so commendably up to date. It will be noted with surprise, for instance, that not only does he advise the alveolar puncture in maxillary antrum suppuration, but that he actually permits the sacrifice of a sound tooth if necessary for the accomplishment of this measure.

The handling of the details of the etiology, symptomatology, and medical treatment of the various diseases is, in general, careful and complete; but too little space for a volume of this size has been given to the description of operations. Here, also, we are disappointed to find that several recent developments do not receive an amount of attention commensurate with their popularity. Submucous resection of the nasal septum, for example, is dismissed in 21 short lines.

As a suitable anæsthetic in operating for the removal of adenoids Dr. Bruck recommends ethyl bromide, a compound which few English anæsthetists would care to use, for certain good and sufficient reasons.

The volume is well bound and presents a handsome exterior. The illustrations are many and useful, and there is a fair index. So that, on the whole, we may say that if the "practician" is able to ignore the uncouthness of the translation he will find Dr. Bruck's text-book of some value.

---

*Dental Surgery and Pathology.* By J. F. COLYER, M.R.C.S. Eng., L.R.C.P. Lond., Dental Surgeon to Charing Cross Hospital and the Royal Dental Hospital. Being the third edition of "Diseases and Injuries of the Teeth," by MORTON SMALE and J. F. COLYER. London, New York, Bombay, and Calcutta: Longmans, Green and Co. 1910. Pp. 1000. Price 25*s.* net.

THE great advances made in the study of general pathology have naturally influenced the study of special departments of medicine and surgery, and the pathology of the teeth has participated in the general progress. The text-book of "Diseases and Injuries of the Teeth," by Mr. Morton Smale and Mr. J. F. Colyer, achieved no small measure of popularity, and now Mr. Colyer has written the work before us which appears practically as the third edition of the book we have mentioned. It has been the aim of the author to describe the most modern aspects of dental pathology and to describe the treatment of the morbid affections of the teeth as based on our present knowledge of the etiology and pathology of dental disease. In this work the author has been fortunate in obtaining skilled assistance in certain special departments; thus Mr. H. S. Clogg has assisted in the preparation of the chapter on tumours of the jaw, a subject too little regarded in many text-books on dentistry. The importance of this matter will only be fully appreciated by considering the fact that the dental surgeon is often the first trained observer who has an opportunity to examine the interior of the mouth soon after the appearance of a new growth, for the patient naturally is inclined to ascribe the pain to some dental condition. Therefore it is essential that every dentist should be capable of recognising and appreciating the importance of the earliest manifestations of new growths. This chapter is well written and should prove of value to the dental student.

Mr. Kenneth W. Goadby has completely rewritten the chapter on the bacteriology of the mouth, and all medical authorities are now agreed as to the immense importance of septic oral conditions on the general health. All morbid processes in the teeth react on the general health, and probably the most important of these is that which is most commonly known amongst medical men as pyorrhœa alveolaris, but Mr. Colyer prefers to call it chronic general periodontitis. He considers that the initial cause in the majority of instances is an injury to the tissues of the interdental stratum by fermenting food and other decomposing débris. Infection with pathogenic organisms rapidly follows, and the author holds that the chronic character of

the process is one of slow tissue necrosis rather than acute inflammation, and that the disappearance of the alveolar margin is due to the action of toxins which are formed in the pockets around the teeth. He believes that the tissues round the alveolar process are unduly liable to attack on account of a lack of functional activity the result of inefficient mastication, and he considers that the calculus on the teeth is a product of the discharge from the teeth sockets, and that it does not affect the disease beyond interfering with the cleansing of the pockets round the teeth.

A list of the papers which have been found useful in the preparation of the work has been added to many of the chapters, in order that anyone desiring to study specially that particular subject might be able to refer easily to the authorities. Many illustrations are supplied, in all nearly 900. They are well selected and clear.

The book is primarily intended for the student and practitioner in dentistry, but there is much in it that should prove of interest and value to the medical practitioner, and, indeed, it would be desirable if practitioners of medicine knew more than they usually do of the affections of the teeth, for they would be in a better position for recommending their patients to apply for the assistance of a dentist when necessary. Only too many members of the public are under the impression that there is nothing the matter with a tooth unless it aches. We can speak with confidence in praise of the book, and we hope that the success which it merits will be attained.

---

*Popular Drugs: their Use and Abuse.* By SIDNEY HILLIER, M.D. Edin. London: T. Werner Laurie. Pp. 192. Price 3*s.* 6*d.* net.

WE learn from a note on the loose cover of this work that "it is the object of this book to give in popular form some account of the legitimate sphere of this class of drugs (i.e., those leading to a drug habit) to show the dangers of excess, to point out some of the preventive measures against excess, and the best and most modern methods of treatment." As a rule, we think that popular books on medicine do more harm than good, for they lead the lay reader to put a confidence in his own judgment which is but rarely justifiable. However, if a popular book on medicine or medical matters is to be written, it is better that the author should be a medical man than that the book should be written by a "health lecturer" or a school teacher.

Dr. Hillier deals first with alcohol, and then successively with tea, coffee, cocoa, opium, tobacco, Indian hemp, mescal, cocaine, hypnotics, analgesics, and patent medicines. The remarks on alcohol are in general characterised by soundness, though here and there we note inaccuracies. For instance, we do not think it correct to say "Sherry contains 23 per cent. of alcohol" without some modification, for there are some sherries which do not contain anything like this amount. Neither is any information given as to whether the alcohol is calculated by weight or by volume, and for the purposes of comparison it should be one or the other, not both. On p. 65 we note a dietetic regulation with which we cannot agree, where Dr. Hillier says that for a gouty person well-kept fine quality Bordeaux, freely diluted with an alkaline mineral water, is permissible. The dilution should certainly be done in the stomach and not in the tumbler—that is to say, the water should first be drunk and then the "fine quality Bordeaux" can be enjoyed in the ordinary way. Not enough stress is laid on the difference between the effect of ethylic alcohol and that of the vinous ethers which are found in good wines and brandies. Ethers are valuable as stimulants.

In speaking of tea Dr. Hillier says (p. 102): "Hard water does not make good tea ..... a pinch of bicarbonate of soda should be added before the tea is introduced. Soft water extracts more of the soluble principles of the leaves." If a hard water is used much of the tannin is thrown down in the form of tannate of lime, and probably caffeine is set free from its combination and in the free state it may be mischievous. Bicarbonate of soda may do the same thing.

Dr. Hillier's remarks upon self-drugging, hypnotics and patent medicine are good, but the public at large is so silly as regards its health that so long as hypnotic drugs are allowed to be sold freely over the counter, and so long as every kind of quack remedy is advertised in papers and magazines, for so long will weak-minded persons continue to ruin their health and waste their money. We are in accord with Dr. Hillier's remark that the question as to whether drugs are to be condemned "entirely depends on whether their use is regulated and controlled by knowledge or by ignorance."

Dr. Hillier has approached the various subjects indicated from the excellent standpoint of common sense.

---

*Traité Pratique d'Électricité Médicale.* By Dr. J. LARAT. Paris: Vigot Frères. 1910. Pp. 641. Price 10 francs.

THIS is the third edition of a handbook on medical electricity by Dr. Larat of the Hôpital des Enfants Malades of Paris. The chapter on electro-diagnosis is very complete, and is well illustrated by tracings of the actual curves of muscular contraction. The curves of normal faradic and galvanic excitation respectively are of great interest. They are obtained by means of Dr. Larat's apparatus for graphic electro-diagnosis, which consists of a revolving drum, on which are recorded the muscular contractions by means of a tambour as is usually done in the physiological laboratory. This is an ideal method of recording the comparative excitability of the same muscle on the sound and on the affected side, but is too complicated to be used in ordinary hospital routine. Bergonié's charts are commended for registering the results of muscle testing, and if this is done in two colours, red for the make and blue for the break, no better scheme could be devised.

In a later division of the book Dr. Larat has coined a new term, Electro-clinique, which includes all methods of electrical treatment. In the article on uterine fibroma he states that he has totally given up Apostoli's and Tripier's methods in favour of the treatment by Roentgenisation, with which he has obtained encouraging results. As might be expected from a work by the author, it is very much up to date, for Dr. Larat is in the van of modern electrical medicine. For instance, in the article on the treatment of adiposity we find reference to Guilleminot's method by galvanic currents of high intensity and to Bergonié's excellent results by the faradic current, or by rhythmic galvanism. The author is also a great advocate of the hydro-electric bath, which he uses with effect for gout and obesity, while among other therapeutic points we may notice the use of high-frequency sparking in the treatment of varicose ulcer, and the introduction of salicylic ions in rheumatic affections of the joints. The article on paralysis is very long and gives the result of the author's large experience. It is perhaps the section best worth studying of all in the book.

There are a few misprints, but the illustrations are numerous and well chosen, and there is a most excellent index.

---

*The Encyclopædia of Sport and Games.* Vol. I. Edited by the Earl of SUFFOLK AND BERKSHIRE London: William Heinemann. 1911. Pp. 496. Price 12*s.* 6*d.*

THE first volume of this admirable encyclopædia covers the space between aeronautics to cricket, and the title of the very first article indicates how wide the meaning of the word "sport" is now to what it was ten years ago, when the original edition of this encyclopædia was

issued. To-day, as the editorial preface says, artificial locomotion on the land and in the air has made such giant strides and become so much a subject of competition and emulation that there cannot be any further doubt of its proper place in an encyclopædia of sport. The article on aeronautics is written by Lord Montagu of Beaulieu, editor of *The Car*, and one of the earliest and most expert motorists in the kingdom. It is a highly interesting and readable summary of aerostatics, to which is appended a bibliography ranging between 1784, the days of the exploits of M. Blanchard and M. Lunardi, to the numerous accounts of flying machines which have appeared recently since M. Santos Dumont's story of his airships was published in 1904. The article is profusely illustrated with reproductions from photographs depicting, for instance, M. Blériot's arrival at Dover on July 25th, 1909; Messrs. Latham and Farman flying at Blackpool; Mr. Wilbur Wright (whom Lord Montagu regards as the first successful inventor of a flying machine fitted with an engine); the Comte de Lambert and M. Gobron; M. Paulhan winning the London to Manchester contest; and all forms of balloons from the Montgolfier machine, which made ascents in August, 1783, to Zeppelin II. in full flight over Lake Constance and the first flight of the new Russian airship Russie. Among other articles there is a symposium upon atheletics, to which past champions like Mr. C. L. Lockton, Mr. C. B. Fry, Mr. M. Shearman, and Mr. H. Wade contribute. Billiards and coursing are the subjects of exhaustive contributions. There is much talk of fishing and shooting under such alphabetical heads as big game, bison, bear, black game, bass, bream, chubb, carp, conger, and River Conservancy. Cricket is dealt with under subheads, which can be easily guessed, by the Jam of Nawanagar, Mr. F. G. J. Ford, Mr. T. Richardson, Mr. B. J. T. Bosanquet, and Mr. M. C. Kemp, Mr. W. J. Ford being general editor. The encyclopædia is profusely illustrated with reproductions from photographs, with line engravings and diagrams, and contains also eight finely coloured prints. The work is sure to appeal to many of our readers; automobilism, fully dealt with here by Lord Montagu of Beaulieu, is now regarded by many medical men as part of their necessary technical education, while there are few of us who have not some form of sporting pursuit.

## LIBRARY TABLE.

*Practical Physiological Chemistry.* By R. H. ADERS PLIMMER, D.Sc., Assistant Professor of Physiological Chemistry, University College, London. With coloured plate and other illustrations in the text. London: Longmans, Green, and Co. 1910. Pp. 270. Price 6*s.* net.—Dr. Plimmer has given us in this book a clear and attractive account of the practical side of physiology. His experience as a physiological teacher has endowed him with the faculty of presenting facts in logical sequence and in simple terms. He knows exactly the essentials of the subject for the student and he has carefully guarded against overloading his account of laboratory applications with general considerations. In a word, he has successfully written of essentials within the due limits of a handbook. The following is worth quoting as a very good example of what the American would call "straight" writing. Under the heading of "Life Cycle of the Elements," the section in which it occurs contains this preliminary paragraph: "During the life processes of animals and plants an interchange of inorganic into organic and of organic into inorganic compounds occurs. The change of inorganic into organic is effected by the plant from the carbon dioxide of the atmosphere, ammonia and salts in the soil. The change of organic into inorganic is effected by the animal. The organic compounds synthesised by the plant enter the animal as food, and are converted into carbon dioxide which leaves the body by the lungs, salts, urea, and other simple organic compounds which leave the body in the urine. The fæces contains matter which has not been utilised by the animal. The urea and the other organic compounds in the excreta are finally broken down into carbon dioxide, ammonia, &c., by bacteria. There is thus a complete life cycle of the elements." What a great and forcible story is indicated here in a few words. The practical directions to the student are excellent throughout and the book altogether may be commended with the greatest confidence.

*Gall-stones and Diseases of the Bile-ducts.* By J. BLAND-SUTTON, F.R.C.S. Eng., Surgeon and Lecturer on Surgery to the Middlesex Hospital, and Member of the Cancer Investigation Committee. New and revised edition. With 53 illustrations. London: James Nisbet and Co., Limited. 1910. Pp. 256. Price 4*s.* 6*d.* net.—We were able to speak favourably of the first issue of this book, and we find that this revised edition presents clearly the advances which have been made during the five years that have elapsed since the first appearance of the work. Mr. Bland-Sutton considers that the opinion which was formerly generally held, and is still held by many, that many diseases associated with gall-stone are due to infections ascending the bile-ducts from the alimentary canal is false, and he maintains that many septic diseases of the bile-duct are caused by infection from organisms eliminated from the blood of the portal circulation and discharged into the outgoing bile; thus, according to his view, most of the disturbances which come under the surgeon's hand in connexion with the biliary passages are "descending infections." This opinion is certainly gaining credence, though perhaps it is expressed a little dogmatically here. Within recent years we have learned that malignant disease of the gall-bladder is more frequent than used to be thought, and the author considers that the association of cancer and gall-stones indicates that these two conditions are manifestations of a common cause, and he believes that this association strengthens the position of those who believe that cancer is due to a micro-parasite, probably taken into the alimentary canal with food and water. The book is very suggestive of the originality of its author and is well worth reading. The illustrations are excellent, as they always are in any work by Mr. Bland-Sutton.

*Hay Fever and Paroxysmal Sneezing (Vasomotor Rhinitis).* By EUGENE S. YONGE, M D. Edin. Edinburgh and London: William Green and Sons. 1910. Pp. 150.—Those who are acquainted with Dr. Yonge's previous publications have learned to expect that whatever comes from his pen will be both scholarly and readable. To expect also novelty when such well-worn subjects as hay fever and its congeners form his theme is, perhaps, to ask too much. Although, however, the author has broken but little new ground, the book, as a handy compendium of views on the whole subject, thoroughly deserves a prominent place in the practitioner's library. There are only two minor details upon which we desire to utter a word of criticism. Dr. Yonge very properly devotes a considerable amount of space to the important matter of the treatment of hay fever, but in our opinion he would have considerably enhanced the value of this section if he had discriminated rather more clearly and emphatically between the less and the more successful methods. The other point is, that his warm support of the treatment of paroxysmal rhinorrhœa by shaving off the septal tubercles does not, as far as we are aware, represent the opinion of rhinologists in

general. The coloured plate which is supplied to illustrate this operation is, by the way, not very educative.

*Indiscriminate Spitting and the Prevention of Consumption.* By C. CONYERS MORRELL, L.R.C.S. Edin. London: W. Speaight and Sons. 1911. Pp. 16, paper. Price 2*d*.—Any paper forcibly and yet sensibly written on this subject for the enlightenment of the public is worthy of commendation. This is such a paper. The author shows a broad grasp of first principles when he writes that it is the unquestionable duty of every priest and minister, of every statesman and every public man, to study and understand the doctrine of infection and proclaim the fundamental principles of prevention and the necessity for their observance.

## JOURNALS AND MAGAZINES.

*The North American Review.*—The January issue contains a plea by Olivia Howard Dunbar for the State acknowledgment and fulfilment of the duty of guardianship to the child. She points out how for the past 25 years or more, whether as scientists, as artists, or as sentimental amateurs, we have been more or less profitably engaged in "studying the child," as a result of which many "wise effective agencies," that will in time be greatly multiplied, are already in operation. The work of the New York City Department of Child Hygiene, under the direction of Dr. Josephine Baker, the child labour committees, the juvenile courts, the tendency to substitute outside family boarding for orphanages and children's homes, are all reviewed, and the article concludes with a statement of the purpose of the Child Welfare Exhibit, being held in New York City during the current month. As a result of an investigation of child-life in New York a display of various conditions affecting child-life and health, with the deductions to be drawn therefrom written very large and conspicuous indeed, in the manner of recent years rendered familiar by the tuberculosis exhibitions, is endeavouring to reach the untrained mind that is too indolent or too weak in its mental digestion to assimilate any but predigested food. A Bill, it appears, is now before Congress recommending the formation of a Federal Children's Bureau under the Department of the Interior. In other articles in the same issue of a magazine that is always interesting, John Brown of American fame is painted respectively as "if no saint, always a hero and a martyr," by W. D. Howells, and as an "assassin" and a "death dealer," "without a gleam of human love or pity for myriads of his own race, his countrymen who happened to have been born and to have lived south of the line of Mason and Dixie," by Henry Watterson; Max Eastman tells us why woman suffrage is important; under the heading of Personalities and Political Forces, Albert Bushnell Hart stumps for Roosevelt in the Presidential campaign of 1912; and "Britannicus," writing in the midst of the battle of the recent British elections, arrives at the sane conclusion "that the tremendous issues now confronting the British people cannot be permanently settled except by consent."

*Edinburgh Medical Journal.*—The January number of this journal opens, so far as original matter is concerned, with a paper by Professor F. M. Caird on Epithelioma of the Tongue, based on a review of 60 hospital cases. Sixteen patients are still alive. The writer recommends local anæsthesia for the first part of the operation. In an opening address before the Edinburgh Obstetrical Society Dr. F. W. N. Haultain discusses the comparative progress of midwifery and of gynæcology, the former remaining almost *in statu quo*, while the latter has made great strides. Mr. David M. Greig writes on Recurrent Enlargement of the Salivary Glands, a condition little noted in text-books. It seems sometimes to be a sequel of mumps and may be due in some cases to obvious affection of the duct, whereas in others its causation remains quite obscure.

*The Dublin Journal of Medical Science.*—A moderate and unbiased discussion of the physiological effects of alcohol is so seldom encountered that one must record the appearance of a paper answering to this description almost with astonishment; yet such seems to be the nature of Dr. W. H. Thompson's contribution on the subject to the December number of this magazine. It is, however, rather short and sketchy. In the same issue is published an interesting address by Professor E. J. McWeeney on Some Tendencies of Modern Research in Veterinary and Human Medicine, in which, among other things, attention is called to the existence of ultra-microscopical infective agents and to Borrel's view that some forms of epithelioma may be due to such a virus, carried perhaps by the parasite Demodex folliculorum.

*The Medical Chronicle.*—In the January issue of this journal Dr. W. B. Warrington discusses the diagnosis and prognosis of traumatic neurosis, and notes the difficulty met with in many cases in which the best form of treatment demands that the patient should occupy his mind with work, whereas he is claiming compensation legally for inability to follow his ordinary occupation. Dr. W. Mair writes on enlarged thymus and records a case in which after death there was found waxy degeneration of the heart muscle; and Dr. Alan McDougall discusses the treatment of status epilepticus, noting the importance of watching for the occurrence of hyperpyrexia and treating it at once when present, and advising the withholding of all food from the patient, but administration of plenty of water.

*The West London Medical Journal.*—Literature is rapidly accumulating on the subject of the Ehrlich-Hata remedy for syphilis, generally known as "606." In the January issue of this journal Mr. J. E. R. McDonagh gives a very interesting account of the steps which led to its introduction and to the experimental work done with it on animals. He also discusses its therapeutic use and notes the fewness of the accidents which have followed its administration. Dr. Reginald Morton writes on X ray examination of the urinary system and describes the technique advisable for the purpose, and Mr. J. D. Mortimer contributes a paper on the selection of anæsthetics for various types of patients and forms of operation.

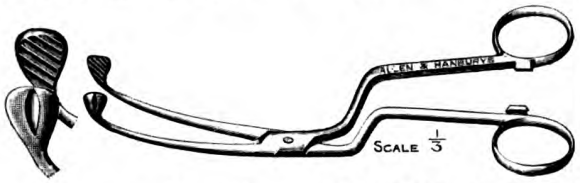
*The Birmingham Medical Review.*—The original matter in the December issue of this review is entirely gynæcological. Sir J. Halliday Croom, in an inaugural address to the Midland Medical Society, deals with the narrow pelvis and lays emphasis on the necessity for maternity homes for the conduct of labour, which differs so little in many cases from a surgical operation. Professor R. F. C. Leith's Ingleby lectures on Tumours of the Body of the Uterus are continued, the present instalment dealing with sarcomatous degeneration of fibroids and with sarcoma and deciduoma malignum of the uterus.—In the January number is contained a paper by Mr. Leonard P. Gamgee on the operation of lymphangioplasty as devised by Mr. W. Sampson Handley and a summary of a post-graduate lecture by Dr. James E. A. Sawyer on Chronic Affections of the Lungs in Children, in which he notes the rarity of any condition resembling adult pulmonary tuberculosis in children under 12 years old.

UNIVERSITY COLLEGE LABORATORIES FUND.—Lord Iveagh has promised to increase the donation of £250, which he has already given to the University College Chemical Laboratories Fund, to £1000. Over £19,000 have been collected for the Fund.

# New Inventions.

## IMPROVED FORCEPS.

THE accompanying illustration shows a forceps made to my design by Messrs. Allen and Hanburys, of 48, Wigmore-street, London, W., to facilitate the performance of Kocher's invagination operation for the radical cure of inguinal hernia. As will be noted, the shaft of the forceps has a gentle curve bringing the head to the level of the handles. The head is bullet-shaped, bearing a slot on either side. The head of the forceps carrying the invaginated sac protrudes the parietal



peritoneum into the opening made by separating the fibres of the internal oblique and transversalis muscles, and here it is secured. Through the button-hole now made in the peritoneum the sac is very readily picked up by inserting the teeth of a tenaculum forceps into the slots in the head of the hernia forceps. The forceps have proved very satisfactory and render the performance of this excellent operation very simple, and if working single-handed or on a muscular subject they are invaluable.

HARRY CRICHTON, M.D., B.S. Durh.,
South Shields. Assistant Surgeon, South Shields Infirmary.

## POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.

A COUNCIL meeting of this association was held at 34, the Copthall-avenue, London, E.C., on Jan. 20th, and chair was taken by Surgeon-General G. J. H. Evatt, C.B., President of the association. The following matters, among others, came before the council. The honorary secretary submitted a letter from a provincial member asking for advice under the following circumstances. He had been appointed medical officer to a certain district with a permanent tenure of office, but had inadvertently moved out of his district by a few hundred yards. He hoped that he would have no difficulty in getting re-elected periodically when his term of office periodically expired. In this, however, he was disappointed, for he had lately had notice that he would not be re-elected at the expiry of his present term of office. The council were of opinion that it was very unwise to act in this manner. By so doing this officer had placed himself entirely in the hands of the guardians and must lose his office unless he could induce his guardians to re-elect him. It could not be too strongly impressed on district medical officers that they could only have security of tenure in their office throughout the country generally *so long as* they resided in their districts.

A letter was read from another member complaining that his guardians had objected to a surgery he had constructed adjoining his house on the ground that it was not built of brick and roofed with slate, although they had permitted the use of similar surgeries by other medical officers in the union. The council considered that this was a matter for the sanitary authority, and if the latter saw no objection to the construction of the surgery the guardians had no right to object.

Another letter was read from a country member, 65 years of age, who stated that he held a second Poor-law district outside his own union, and after holding it for 11 years he was now called upon to resign it. Could he claim any pension on account of it without resigning his other Poor-law appointments, as he had had deductions from his salary for this appointment? The Council considered that he should resign all his appointments and take his pension on the whole if he wished to insure himself against loss, as he was not entitled to any pension so long as he held any Poor-law appointment.

A letter was also read from another member dealing with the same point, but in this case he had not reached the age for retiring, and had held the outside appointment for 13 years. In this case it appeared that the officer would be bound to forfeit all his deductions of salary under the Superannuation Act unless he could retire within the next four years, as only the average salary during the last *five* years could be estimated in fixing the pension. The Council thought this very inequitable, and that such an appointment ought always to be allowed for in reckoning the retiring pension, or that at least the officer should be entitled to claim a return of all deductions from the salary of that appointment for superannuation purposes.

Another country member wrote that the guardians of his union had sent round a circular stating they had decided that the present salaries of the medical officers should be fixed as a "maximum" for their appointment. Could the guardians fix such a "maximum"? He also asked if it were legal for the district medical officers of a union to contract out of the special fees for operations, &c., laid down by the general order of 1847. The council was of opinion that in neither case would this be legal unless with the consent of the Local Government Board.

The honorary secretary reported that he and the other delegates of the association had been present at the first meeting of the Poor-law Conference held at Norfolk House on Dec. 9th last.

It had there been decided that each section of the Poor-law Service should formulate through its respective association what reforms it considered necessary for the betterment of its particular service. He had forwarded to the conference all the resolutions that had been duly passed up to the present, but he thought it desirable that the various points of medical Poor-law reform should be put forward in more detail, especially as a Departmental Committee had been appointed by the Local Government Board to revise the General Orders.

After a careful consideration the council decided that the following recommendations should be put forward on behalf of the Poor-law medical officers of England and Wales:—

1. That the provisions of the Metropolitan Dispensaries' Order, as far as possible, should be made to apply to the country generally, and that all appliances and drugs for the use of State patients shall in all cases be provided at the expense of the State.
2. That there should be a revision of the scale of payments for operations, and more facilities granted for obtaining assistance, and paying for the same. This specially applied to the provision of an anæsthetist. The medical officer should not be at the mercy of the Poor-law authority with regard to this assistance: it should be left entirely in his hands, with only some reasonable check to prevent abuse.
3. In all cases where called in to attend a confinement in his official capacity he should have an inalienable right to his fee. If the case be an improper one from a Poor-law point of view the authority should be left to recover payment from the husband.
4. The Poor-law authority should be compelled to contract with the workhouse medical officer or superintendent of infirmary to vaccinate all infants in the workhouse or infirmary and to carry out the Vaccination Acts generally.
5. The notification of measles and whooping-cough should be carried out in the same manner as has been recently adopted in the case of tuberculosis of the lungs.
6. The salaries of Poor-law medical officers should be on a more liberal scale, due regard being taken of the average mileage in the case of visits to sick patients. That to meet exigencies of changes of population the medical officer should always have a right to claim a revision of his salary when his work has been greatly increased by such change.
7. That an allowance should be made by the Poor-law authority for the carrying out of the Poor-law work of a medical officer during his annual holiday and during sickness.
8. That length of service, as in other public services, should constitute a ground for increase of salary, apart from other considerations.
9. That a common fund be instituted to receive all payments under the Poor-law Officers' Superannuation Act, so that the expense of pensions should not directly fall on a particular locality.
10. That in all cases where for public reasons the office of a Poor-law medical officer is determined, if he or she be not entitled to a pension, an allowance shall be made of a sum equal to the average emoluments derived from that office during the period of two years. Provided always that such determination be not due to misconduct on the part of the officer.
11. That in no case shall it be lawful for the local Poor-law authority by bargaining with individual medical officers to reduce the amount paid at any time annually in medical salaries for attendance on its poor, unless it can be clearly shown that owing to local changes the sickness claims have very materially diminished in that area.
12. That in all cases where, owing to residence outside his district, a medical officer has only been appointed for a year or a term of years, if the said appointment has been continued for a period of seven or more years the said medical officer shall thereafter be entitled to hold office on the same terms as if he resided in his district.

# THE LANCET.

*LONDON: SATURDAY, JANUARY 28, 1911.*

## Annual Report of the Medical Officer of the Local Government Board.

SHORTLY after Christmas the annual report of the medical officer of the Local Government Board for 1909–1910 was published. As year by year we peruse these valuable volumes we cannot help wondering whether it might not be practicable to issue one annual report, not only upon the British Isles as a whole, but also upon the health conditions of the empire. But we fear that this might prove a difficult matter, and perhaps, after all, the different practices which obtain in Scotland and in Ireland furnish us with comparative studies from which each local government authority selects that which best suits its needs; although, on the other hand, there is in certain directions necessity for more uniform action in the three divisions of the United Kingdom than is at present the case. We must confess, too, that we should like to see the annual report of the English Local Government Board embody some sort of summary or review of the health conditions obtaining in Scotland or in Ireland and in the colonies, and perhaps the best means of accomplishing this end would be to make the President of the Local Government Board Imperial Minister of Health, a step which has been often suggested for many reasons, and one which would tend to centralise all information relative to health matters in one Government office. It must not be inferred that we are in any sense disparaging the work of the Local Government Board; rather must we be understood as implying that the work of the medical department has always been maintained at such a high level of excellence that we should like to see its sphere of influence materially extended.

The report just issued differs but little from its long line of predecessors; it contains an introduction by Dr. ARTHUR NEWSHOLME, the medical officer, reports by the medical inspectors, some of which have been already published and have been reviewed in our columns, memoranda issued by the Board upon various subjects, increasingly depressing figures relative to the administration of vaccination, and, finally, an account of the auxiliary investigations carried out during the year. As it is our intention to deal in one or more special articles with some of the more interesting features of the report we shall here mainly confine ourselves to an indication of the general scope of the volume. The most interesting innovation is a review by Dr. H. FRANKLIN PARSONS, the senior assistant medical officer, upon epidemic diseases in England and Wales during 1909, a contribution which really amounts to a sketch of the behaviour of measles, whooping-cough, scarlet fever, diphtheria, enteric and typhus fevers, small-pox, influenza, and epidemic diarrhœa over the years for which reliable figures are available. Dr. PARSONS, the author of classical works upon disinfection, influenza, and many other subjects, is well qualified for supplying reviews of this character, since his intimate knowledge of epidemiology and cyclical waves of disease enables him to avoid the pitfalls into which more superficial workers are so liable to be precipitated owing to too restricted a review of the past history of disease. It is much to be hoped that these annual reviews will be continued, although we are afraid that Dr. PARSONS, who, we believe, is approaching the age limit of the Civil Service, may not be much longer available for the purpose. But possibly in his well-earned retirement after so many years of silent service he may, unfettered by the exigencies of office, take up his pen and write of epidemiology. Dr. R. BRUCE LOW contributes, as in past years, his useful summaries of the progress of plague and cholera, and his review as to plague progress and prevalence makes especially interesting reading at the present time owing to the tendency of this disease towards general diffusion. Dr. S. W. WHEATON, one of the inspectors, furnishes an interesting report upon enteric fever prevalence in the county of Durham, and this has already, we believe, been published.

Dr. G. S. BUCHANAN reviews the work of the food inspectors, dealing with the action taken under the Public Health (Regulations as to Foods) Act, 1907, the local arrangements made for meat and food inspection, work in relation to the Sale of Food and Drugs Acts, and foreign and colonial food legislation. Dr. BUCHANAN'S report is reviewed in another column of this issue of THE LANCET. Dr. J. C. G. LEDINGHAM'S report on enteric fever carriers is also embodied in the volume before us, and this was fully reviewed in our columns when it was first issued.[1] Amongst what are known as the auxiliary scientific investigations is a report of work carried out by Dr. F. W. ANDREWES upon the behaviour of the leucocytes and the changes in the bone marrow in relation to infection. Numerous organisms were subjected to test during the course of the experiments, and the general conclusions arrived at show that the human economy responds in different fashion according to the nature of the organisms employed—that is to say, that the method of defence depends upon the character of the attack. Dr. W. G. SAVAGE has continued his investigations upon the Gaertner group of bacilli in prepared meats, and the later experiments have tended to emphasise the former conclusions that outbreaks and isolated cases of food-poisoning are due to specific infection of the food and not to non-specific excretal contamination. The important subject of the bacterial measurement of milk-pollution is also dealt with by Dr. SAVAGE, who is of opinion that the most reliable inferences can be drawn by estimating the number of bacillus coli and its near allies, and of the spores of the bacillus enteritidis sporogenes, as well as of a microscopical examination of the centrifugalised deposit. We are glad to see, too, that Dr. SAVAGE advocates that bacteriological examination shall be carried out side by side with inquiries at the sources of the supply of the milk. The chemical aspects of epidemic diarrhœa have been investigated by Dr. H. A. SCHÖLBERG and Mr. MACKENZIE

[1] THE LANCET, Dec. 3rd, 1910, p. 1631.

WALLACE, who have endeavoured to discover in milk chemical substances which, due to bacterial metabolism, are able to stimulate the secretory functions of the gastro-intestinal canal. The authors conclude that the presence of the peptones and peptone-like bodies may explain the reaction of the infants' gastro-intestinal tract to certain microbial infections. They found that during the summer months peptones were present in milk samples in large quantities whenever the samples yielded a higher bacterial count.

The possibility of purifying chalk waters by chemical methods is a very important consideration in view of the growing opportunities for the pollution of these waters which arise in consequence of the extension of human habitations over uncovered chalk areas. It was therefore decided that Mr. C. E. MOORE and Professor HEWLETT should carry out some investigations with respect to the sterilisation of chalk waters, and it was found that such sterilisation could be effected under laboratory conditions by adding 0·25 part per million of bleaching powder and allowing the action to continue over half an hour. But as to this, Dr. NEWSHOLME in his introduction remarks that these experiments in no sense justify sanitary authorities in refraining from every effort "to minimise and remove cesspools and other sources of pollution in their gathering areas, while trusting to treatment by chlorine, ozone, and other chemical means of purification." We are in full agreement with this sentiment, and it is clear that these chemical means of purification must, at any rate for many years to come, be regarded as merely supplementary agencies and not as substitutes for securing the sources of supply against pollution.

Dr. NEWSHOLME reports that up to October, 1910, 51 local authorities had received the sanction of the Local Government Board to add ophthalmia neonatorum to the list of diseases notifiable under the Infectious Diseases (Notification) Act. With respect to preventive measures against tuberculosis the medical officer states, on the basis of the annual reports of medical officers of health, that the order providing for the notification of pulmonary tuberculosis amongst paupers has in several districts been taken advantage of and good work carried out under its provisions, more especially in districts where means exist for helping the patients. Considerable space is devoted in this introduction to the subject of infantile mortality and Dr. NEWSHOLME emphasises the part played by alcoholism in this direction. He also summarises the report upon infantile mortality, which was issued as a separate paper and which we noticed in full in our columns at the time.[2]

## Sir Francis Galton.

THE death of Sir FRANCIS GALTON deprives England of a type of man of science not easily to be replaced. Maternally descended from the DARWIN stock, and hence a conspicuous illustration of a doctrine which he did much to confirm and popularise, he was conspicuous throughout his long life by that habitual preference of truth to system which is characteristic of the philosopher, and by that constant respect for the opinions of those who differed from him which is characteristic of the gentleman. His habitual caution rendered him almost exempt from the errors which are incidental to haste, and his habitual moderation rendered him almost exempt from the errors which are incidental to uninformed and presumptuous judgment. Always kindly, always dignified, always urbane, he received with gracious courtesy the inquirer who would investigate the basic facts of his doctrines; and he was always ready to place the stores of his memory and the fruits of his researches at the service of the genuine student. He met irrelevant criticism with a genial smile; and the infirmity of his later years enabled him, on more than one occasion, to imitate with much effectiveness the example of REYNOLDS:

> "To coxcombs averse, yet most civilly steering,
> When they judged without sense he was still hard of hearing."

The work of the earlier portions of a life which for something like 65 years was mainly devoted to scientific inquiry has, almost of necessity, become enshrined among the accepted truths of to-day, and is now hardly remembered in its detail. There are still a few elderly men who can recall the sensations with which they first read "The Art of Travel," with its infinite variety of devices for warding off the dangers or for obviating the discomforts of the wilderness; and there must be many more who remember the groundwork of modern meteorology which was laid in the years between 1860 and 1870. But the turning points of GALTON'S career, as far as the general public were interested in it, were his studies of finger-prints and of the hereditary character of intellectual ability. The idea once seized, that the papillary ridges of every individual present individual peculiarities, scope was at once given for the exercise of the untiring diligence and the unsleeping caution which were the main elements of the philosophical side of his character, and the whole matter was in due time worked out to its conclusions, and was rendered available for the many practical purposes to which it has since been applied, including, among others, a greatly increased patronage of the glove trade by the professors of the art of burglary. But the question, calculated though it was to arrest attention, was only a by-product of GALTON'S diversified ingenuity. He did not claim to be the originator of finger-print reading and he did not suffer its consideration to occasion any neglect of the main idea to which his thoughts had become directed, the idea which he afterwards expressed in the word "Eugenics," and which might be defined as the belief that the average fitness and capacity of the human race may be improved by the practice of selection in parentage. It was for the support and extension of this belief that GALTON founded the research fellowship on the subject in the University of London, and that the Society of Eugenics has since been established by his friends for the better prosecution of the work. He has shown quite conclusively that the family which has produced one member of conspicuous ability has, in the great majority of instances, produced others of like kind, and although some allowance must be made for the increased opportunities afforded to the younger members of a house when one of the seniors has risen to eminence, it seems

[2] THE LANCET, August 6th, 1910, p. 412.

clear that the influence of this cause is by no means sufficient to explain events which are matters of history. It must be taken as a fact that certain families are of distinctly higher type than others, more perceptive, more intelligent, more determined, more persevering; and that, although these also may produce their weak members, the general average will be superior to that of the community at large. The real problem is to ascertain whether differences of this kind, produced at present we know not how, can be produced artificially by any process of mating; and if this be possible, whether the conditions of mating required are of such a kind as to admit of fulfilment in modern society.

To this question, we apprehend, Sir FRANCIS GALTON was prepared, at all events during his later years, to return an affirmative reply. He believed that it would be possible to bring about a general improvement of the human race by selection in marriage, and he looked forward to a future when such selection "will be required by the national conscience, and will become an orthodox religious tenet." The difficulty, as it presents itself to us, is mainly that of instituting the necessary experiments, and of excluding obvious sources of error. The late Mr. HEPWORTH DIXON published, many years ago, a book descriptive of the tenets, social and religious, of a number of queer sects or communities which were existing in the United States; and among these there was one in which marriage was not permitted as an institution, but in which certain couples were selected by the council of the community for the purpose of producing the children necessary for its continuance. Temporary unions for this purpose were only allowed between the young of either sex and the mature or middle-aged of the other, a young man being first mated with a mature woman, or a young woman with a mature man, and each being provided with younger concubines in subsequent years. All the parties to these transactions were required to be in good health; and it would be highly interesting, if it were possible, to ascertain what had become of their descendants. Short of such evidence as might thus be supplied, the chances of error in selective mating seem insuperable. The departures of children from what appears to be the parental standard, in the direction either of improvement or of deterioration, are sufficiently numerous and sufficiently manifest to require a good deal of explanation, and it is evident that the causes of these departures are to a great extent unknown. The Liturgy defines the objects of marriage to be not only the "procreation of children" but also "the mutual society, help, and comfort that the one ought to have of the other," and it would be curious to inquire whether the ordinary methods of selection are calculated to fulfil both these objects with equal efficiency, or whether one of them may not sometimes be sacrificed to the other. Nothing is more curious to a bystander, few things are less explicable, than the ground of selection which induces some particular man to take some particular woman; and it is at least possible that the impulse to selection may sometimes have as much to do with an expectation of mutual help and comfort as with any real congeniality for the purposes of procreation. In other words, the union best calculated to produce vigorous offspring may not be that which is actually brought about by the instincts of the couple concerned. Each may be attractive to the other, and yet it is conceivable that each might produce better offspring with some other mate. In these considerations we have a difficulty which lies at the root of what may be called applied eugenics; and it is a difficulty to be removed, if at all, only by a much more extended and more careful observation of facts than has been yet carried out. Perhaps the medical inspection of school children, when it has been in progress long enough for the proper systematisation of records, may afford valuable data, especially in the direction of light upon the parentage of children who display any tendency to rise out of the class in which they were born. In the meantime much work is being done by our eugenists, who must not, however, expect us to accept their conclusions as yet with great freedom. The practical science of eugenics is still very young, and eugenists must remember that the master whose loss they and we alike deplore, was an uncompromising enemy of hasty generalisation, and a consistent advocate of the slow and careful building up of truth.

## The Relation of the University to the Hospital.

CENTURIES ago, when most even of the oldest universities were comparatively young, and when the great majority of those now existing had not begun to be, a university was supposed to have fulfilled its duty when it had afforded opportunity for its students to acquire all the theoretical knowledge of the day. The practical application of knowledge, or the study of those subjects which deal with practical utility, was not considered necessary; the learning was there, but the application of that learning to everyday work was wanting, for no one had perceived the need of joining up the two things. When hospitals were first started, in this country at least, they had, of course, no connexion with seats of learning; the idea that the principal part of the pious work designed by the charitable founders might well be carried on by persons in touch with the expansion of knowledge occurred to no one for some time. In London, for example, the medical schools, while developing as outgrowths from the hospitals, were much resented by many of the managers of the hospitals. The delivery of lectures to the students and the admission of them to work in the wards were in some instances carried on against opposition, it not being perceived that in this manner only could there be trained up a class to receive the fruit of the medical experience of their seniors. Of course, this time has completely gone by, and no longer is the value of a medical school to a hospital disputed, but, as everyone knows who follows the public discussions which now take place frequently upon medical affairs, the relations between the hospital as a seat of clinical medicine and the university (or scientific corporation) as a centre of learning, are capable of debate.

Medicine in all its branches has undergone enormous progress of late, as it is necessary to point out perpetually. The subsidiary sciences of bacteriology and pathological

chemistry have assumed an importance undreamed of 30 years ago. There has, indeed, been perceived by some critics a tendency to exalt the bacteriologist to a position above that of the clinician, but this, even if it has occurred, is merely a passing phase—a recognition of the importance of bacteriology in modern medicine. Bacteriology has been unduly depreciated in the past, and therefore it is not strange that now, when its value is universally recognised, there should be a tendency to make up for past neglect, a spirit which must not be interpreted as a desire to undervalue the work of the clinician. Professor OSLER'S address on the Hospital Unit in University Work, which we publish in THE LANCET this week, pleads for the fuller equipment of hospitals on the scientific side, for in only too many cases the application of the latest knowledge to the practical needs of the hospital is hampered by want of money. Again, the hospital physician or surgeon, often an extremely busy man, has not the time to devote himself to the original study of bacteriology and pathological chemistry. He has to carry out his arduous clinical tasks and he has in most instances to earn his living. But his work will be incomplete, will indeed be dead, unless he receives that assistance from the newer branches of science which they are able to give him. It is the function of a university, so far as its medical students are concerned, to train the students and to advance research. It is the function of the hospital, not only to treat the patients who come to it, but also to assist in the training of students. The primary function of the hospital is not to serve as part of a medical school, and medical men have never asserted the dependence of the hospital on the school, though they are constantly accused of taking up this position. The treatment of the patients is the primary purpose for which hospitals have been established, but with this treatment the training of students is now so inextricably bound that the one duty cannot be divorced from the other. The training of students is simply a method of making proper preparation for the treatment in the future of patients both within the hospital and without. Money definitely left to a hospital for medical education must not be employed in supporting the patients, and in the contrary position the same respect of the wishes of the charitable public must be observed; but as the best medical treatment is the result of research carried on in medical schools, and as the charitable public desires, of course, the best medical treatment for the objects of its charity, it is clear that the ward and the laboratory cannot be treated as totally unconnected affairs. And, lastly, the services of the students in the direct treatment of the patients are of vast importance, and effect substantial savings in the funds of the great general hospitals. This point should be remembered by those who look only at the advantages offered by the hospital to the student.

Professor OSLER pleads for the fuller equipment of hospitals on the scientific side. He urges that in many instances universities are so much indebted to hospitals that they should assist financially in providing the equipment required, and he sketches the organisation of what he calls a hospital unit. In an ideal hospital each unit would include only one subject, such as medicine, and for this there would be at least 60 beds and at the head the professor of the subject. To it would be attached an out-patient department, and it would possess its own laboratories, which should form an essential part of the unit, though for the sake of economy its work might be merged with the pathological work of other units. He describes the large number of assistants that would be needed for the due carrying out of his scheme, and considers that adequate funds should be provided for the satisfactory progress of the work. It is impossible to retain good junior men in a hospital and to induce them to devote their time to its work and to the teaching of students unless adequate payment is made for their services. Professor OSLER considers that the arrangement at the Johns Hopkins Medical School is good, the university paying half of the salaries of those members of the staff who are directly engaged in teaching and one half of the laboratory expenses. The public does not recognise its debt both to the hospitals and to the university. To the opportunities for studying which are there provided the public is indebted for most of those great advances in medicine which have revolutionised the treatment of disease within the last half century; and this is a debt which the public should pay both to the hospital and to the university. Professor OSLER'S address should do good service in bringing before the medical profession the vast importance which such reorganisation of hospital administration as he projects would have.

# Annotations.

"Ne quid nimis."

## THE LOCAL GOVERNMENT BOARD AND FOOD INSPECTION.

THE Local Government Board has now issued a reprint of the portion of the medical officers' annual report for 1909–10 which relates to the work of the food inspection branch of the medical department, and includes a report by Dr. G. S. Buchanan on the work of the Board's inspectors of foods during the year. The reprint[1] will be of much value to medical officers of health and sanitary inspectors, and has a wider public interest as a record of the progress which has been made by the Local Government Board during the presidency of Mr. John Burns in reforming the methods by which the purity of our food-supplies is controlled and adulteration prevented. The progress to which we refer has been most marked in the case of imported foods. The regulations issued under the Food Regulations Act of 1907 made the port sanitary authorities responsible for the examination of food-stuffs at the place of landing, so that unsound foods can now be dealt with in bulk and their distribution throughout the country prevented. Since the system was introduced there have been many occurrences which have proved its utility; for example, the importation of frozen carcasses of pigs from China which arrived last year in consignments of several thousand carcasses at a time and needed thorough investigation, and the great increase which has lately taken place in the quantity of butchers' "offal"—livers, sweetbreads, kidneys, and similar articles—which is obtained from foreign sources. Some 150 tons of the latter on arrival in 1909 were condemned as unfit for food. In consequence of the regulations

[1] Report on the Work of Inspectors of Foods for the year 1909–10. London: Wyman and Sons, Fetter-lane, E.C.; Edinburgh: Oliver and Boyd; Dublin: E. Ponsonby. Price 4d.

the importation of barrels and boxes full of miscellaneous scraps and trimmings of meat, which a few years ago promised to reach formidable dimensions, has virtually ceased. Fats resembling inferior lard were imported during the year which had been obtained from meat condemned at American packing houses as totally unfit for human consumption. By the American law the packages containing these fats were conspicuously marked "inedible," but they were found to have reached lard refiners in this country. Over 6500 barrels were consequently detained in Liverpool until adequate proof was furnished that the material would not be used for food purposes. At the principal ports at which grain, fish, fruit, and canned foods are landed, a system of "sorting" examinations has been developed. When the preliminary examination of the consignment has shown that it contains articles which are unsound, the consignment is only allowed to go forward after a thorough sorting to the satisfaction of the port medical officer of health. In the London port and riparian sanitary districts, and in the ports of Liverpool and Manchester, more than 400 tons of unsound canned food were handed over for destruction under this system in 1909. It is satisfactory to learn from the report that the examinations thus made appear already to have caused greater care to be exercised at the place of preparation, and have enabled importers to exact a higher standard from the foreign packer. Dr. Buchanan's report shows also that the central department, besides making inspections to see that the examination of food at the ports is conducted on uniform lines, has made numerous inquiries as to the conditions under which foods are prepared abroad. The information which we have published from time to time, as a result of the special investigations which have been made in foreign countries by representatives of THE LANCET, makes it unnecessary to dwell on the importance of this matter. The establishment of a mutual understanding between the authorities abroad and at home in regard to the supervision exercised over the preparation of foods which are to be imported into the United Kingdom is in many cases a necessary adjunct to the examination of the finished articles when they arrive. Other sections of the report deal with local arrangements for meat and food inspection, foreign and colonial food legislation, and work in relation to the Sale of Food and Drugs Acts. As Dr. Newsholme observes, the procedure of the Sale of Food and Drugs Acts is such that it is often difficult to stop misleading descriptions and false labelling of foods, and to repress various trade customs which result in debasing the quality and purity of staple articles of food. The inquiries made during the year in connexion with these Acts included the misuse of formaldehyde fumigation in the preservation of meat and other foods; the failure of the Sale of Milk Regulations of 1901 in Middlesbrough and other towns to secure the supply of milk with even an average proportion of fat; the preparation of "reconstructed" milk; the presence of paraffin in margarine and talc in rice; and the contamination of canned foods by metals.

## THE ROYAL SANITARY INSTITUTE.

A COURSE of lectures and demonstrations for sanitary officers will be held from February to May at the offices of the Institute, 90, Buckingham Palace-road. The course is divided into two parts. The first part will commence on Feb. 13th and close on April 12th, and will deal with elementary physics and chemistry, public health and hygiene; and the second part will commence on April 24th, close on May 5th, and will deal with meat and food inspection. Most of the lectures will be given on Mondays, Wednesdays, and Fridays, and the lecturers will include Professor H. R. Kenwood, Dr. E. Petronell Manby, Dr. Charles Porter, and Dr. E. J. Steegmann. Inspections and demonstrations in connexion with disinfecting stations, dairy premises, municipal depôts, artizans' dwellings, offensive trades, waterworks, common lodging-houses, sanitary works, and refuse and sewage disposal works will take place from time to time. The fee for Part 1 is £2 12*s*. 6*d*., for Part 2 £1 1*s*., or for the complete course £3 3*s*. A course of lectures and practical demonstrations on physiology, personal hygiene, and the sanitation of school buildings and dwellings, principally for the purpose of assisting school teachers, women health visitors, and school nurses, will also be held at the Royal Sanitary Institute on Mondays, Wednesdays, and Fridays, commencing on March 3rd and ending on May 1st. The lecturers will include Mrs. Marion Hunter-Vaughan, L.S.A., D.P.H., Professor Kenwood, Dr. A. Beresford Kingsford, Dr. G. Eric C. Pritchard, and Dr. C. J. Thomas. The fee for the course is £1 1*s*. Both courses of lectures will commence at 7 P.M. Full particulars may be obtained from the secretary, Mr. E. White Wallis, 90, Buckingham Palace-road, S.W.

## THE SHADOW OF A DREAM.

Robert Louis Stevenson has admirably described his sensations during the light-headedness of fever. The kind of mental worry, varied by fatuous contentment, induced by the continued effort to effect something in thought or act, or both—the victim does not know which when properly light-headed—are set forth in the inimitable manner so dear to lovers of Stevenson. It is remarkable that the passage has received so little attention, for it leads us to wonder whether Stevenson ever suffered from any other hallucinations than those here adverted to. Did he, as became an imaginative Scot, ever "see a ghost"? Apparitions are the outcome of a morbid condition of the brain—at least, science mainly, if not always, believes them to be so. It is quite possible that something in the nature of light-headedness precedes all hallucinations, and in this connexion we may quote a letter we have received from a well-known man of letters. "The writer," he says, "may perhaps be forgiven for setting on record a queer little grey experience of his own, which happened within the last few days. He had retired to bed, tired, slightly liverish, and worried by fruitless discussions and money matters—the commonest of psycho-physical syndromata—but had determined to sleep and to think no more of his troubles. To this end he read a historical essay about the murder of Escovedo under Philip II. of Spain, and had settled down to sleep at 11.40 P.M. He remained awake with his eyes shut until midnight, the names and ideas in the tiresomely written article he had just been reading 'running in his brain,' to use the common phrase. At midnight he was again broad awake, and saw standing at the foot of his bed, between him and the still brightly burning fire, what shortly became the shadowy figure, life-size, of a little old woman. She wore a grey shawl and black bonnet, and looked for all the world like one of the neighbouring Kensington Workhouse women. Her face was turned away. The figure, be it said, took shape gradually, and the impression at first was that it was nothing, merely fancy. But on opening and shutting his eyes, moving his head sharply and thoroughly recognising where he was—in bed among familiar objects, &c.—the *Geisterseher* was startled for just the fraction of a minute to find that the figure had taken firm shape and did not move. It was apparently objective and outside himself. It faded away very quickly, and it then became apparent that there was a dark shadow in a corner of the ceiling near where it appeared. It was plainly of the family of dreams, 'the children of the night

without a father,' to quote the old Greek poet. Had it not been a dream-fancy, from beyond the threshold of the subconscious, it would have connected itself with old Spain and Escovedo. As it was, it had nothing to do with recent mental preoccupations, although it certainly personified, quietly and surely enough, the grey and prosaic tenour of the middle-aged existence into which it had come for the first time." Mixed offspring of liver, teichopsia, worry, recent insomnia, and ill-health, the little grey woman will remain a mystery to the writer, so he alleges. None the less, he comes of an ultra-sceptical stock, his father having been a quaternionist and a devotee of dry science, and his great-grandfather a French Jacobin of 1794, famous in his day for his scandalous addictment to the worship of the Goddess of Reason! In accordance with such family tradition, ghosts, apparitions, and the rest must have always appeared to the writer as so many manifestations of primitive thought, and as negligible, therefore, as the belief in luck or magic. Most ghost-seers are unwilling to analyse their feelings and are prone to give way to the excitement of the moment. Hence, doubtless, have arisen innumerable "well-authenticated" ghost stories, which, on analysis, should have proved to be the result of indigestion or overstrain. Savages and primitive people generally, such as the old Highlanders and Lowlanders of Scotland, probably have suffered on occasion from epic dyspepsia.

## A NEW DIAGNOSTIC OF MALARIA.

Dr. C. L. Urriola,[1] writing from Panama, describes a sign of malaria which he terms "new and pathognomonic." As he says in his introductory remarks, the discovery of the parasite in the peripheral blood is a means of diagnosis of the greatest possible accuracy, but with the serious drawback that it is inapplicable to many phases of malaria. There are, for instance, the latent forms of the disease, and the malarial cachexia, conditions in which an accurate diagnosis is of the highest importance, but in which the surest diagnostic sign, the discovery of the parasite in the blood, is not available. Certain methods of diagnosis have, it is true, been brought forward for application to these latent types of paludism in which a search for the parasite in the blood is fruitless; of these Dr. Urriola particularly mentions agglutination tests and urobilinuria. These tests have, however, been proved fallacious, since they do not adequately exclude the presence of other disorders than malaria; and Dr. Urriola in his search for a more reliable test fell back on Laveran's statement that the one constant pathological change in malaria is the presence of pigmentary elements in the blood, a change which has the merit, from the diagnostic point of view, of being peculiar to malaria. At the outset of his researches, therefore, he concentrated his attention on an examination of the plasma for the presence of pigment granules; but this was abandoned as soon as he found that an examination of the urine of malarial subjects discovered the presence of pigment with great constancy. The urine is collected carefully and a specimen is centrifugalised; the deposit is examined under a high magnification. The result, according to Dr. Urriola, is that in the urine of every malarial subject granules of pigment are to be found in one or more of four types. First, there are very fine granules massed together in more or less considerable groups; second, there are rather larger grains arranged in similar groups; third, the pigment may be found in larger masses varying in form; and finally the granules of pigment may be included within leucocytes or hyaline casts. Usually the pigment is an intense black of the Chinese ink type; in many cases blue granules are found, though these form but a small fraction of the total pigment present; and in a few cases yellow-ochre granules are discovered. These can, he claims, be readily distinguished from the translucent yellowish masses dotted with black, red, or brown granules which appear in the urine of persons suffering from other febrile disorders, both by differences in quality and by the much greater abundance of pigment in malarial urines. He illustrates the value of his observations by a relation of several cases whose nature, hitherto obscure, was declared by an examination of the urine, which discovered pigment granules. Investigators are warned that the search may need to be prolonged for half an hour, and that it should include more than one drop of the centrifugalised deposit. He concludes with a statement to the effect that the discovery of black pigment in urine is likely to prove more valuable in the diagnosis of malaria than the observation of parasites in the blood because it is applicable to every type and stage of the disease. It is probable that these statements will undergo modification at the hands of future investigators; but Dr. Urriola's claim is one of so much practical importance that it deserves attention and further examination. Whether his claim to be first in this field will be challenged also remains to be seen; the literature of modern medicine is so voluminous that it is difficult to be safe in a claim to priority.

## CHAMPAGNE AND ITS SIMILARS.

HOWEVER deplorable and inadvisable in their own interests the methods of seeking redress may have been which the peasants in the Champagne district recently adopted, the agitation conveys some lessons of peculiar importance to both the medical man and the public. The destruction of property, of course, is never a justifiable or satisfactory means of obtaining a remedy, but when the facts of the situation are realised it will be seen that a very real grievance existed which led to violent measures being taken. Disaster has fallen upon the vineyards of the Champagne district, as it has upon so many of the vineyards in France, in consequence of the inclemency of the season. The local *vendangeurs* lost their occupation and their means of livelihood. The proprietors sought to replenish their stocks by importing grape-juice from districts outside Champagne in which some grapes were harvested owing to the better weather conditions that had prevailed there through the season. The peasants lost their work, in spite of which wine was being made. They destroyed a good deal of the stock, protesting that the good name and character of the real Champagne product should not be trifled with or endangered in this way. The view they took is entitled to the greatest sympathy; though the means of redressing the evil was crude and not calculated to help them or to settle the industrial problems. The whole incident seems to us to throw considerable discredit on the Champagne industry. It implies that grape-juice need not necessarily come from the Champagne district in order to produce the esteemed qualities of Champagne wine. We do not believe, however, that manipulation can reproduce the inherent natural qualities of the Champagne grape itself from grapes of outlying districts with, at any rate, a success which will satisfy the connoisseur. It is clearly misleading, at all events, to call such a product champagne, and against this we protest. The fine qualities of true champagne are, after all, a matter purely of æsthetic sense, and it can hardly be disputed that sparkling wines produced in other districts and showing a similar composition and soundness to champagne answer, physiologically speaking, equally well. The high price paid for champagne is the price of its elegance and flavour and not of its composition. To produce sparkling wines by the help of grape-juice from districts

other than the Champagne area, which may successfully masquerade as Champagne, is, of course, an art, but the proceeding tends to discredit the genuine article and to lead us to inquire somewhat pertinently as to what is really being paid for in the extravagant prices commonly demanded for champagne. We are certain that many of the honest sparkling wines which are not champagne, and which are sold in this country at a third the price of champagne, are, physiologically speaking, equally valuable. There is very little difference between the composition of, for example, a sparkling Saumur or Medoc and that of a genuine champagne. They may be obtained equally dry, equally free from acid, and equally pleasing to the palate of many people if they happen to be innocent of the brand. The connoisseur, no doubt, readily detects a difference and can easily pick out the real champagne, but he is not the only consumer of sparkling wines. We have examined a number of sparkling wines of the Saumur and Medoc type, and they have yielded results on analysis which are in practical agreement with those given by a champagne. It seems to us that too little credit is given to the sparkling wines produced outside the immediate area of the Champagne districts on a sort of impression that a sparkling wine to be good and wholesome must necessarily be produced in Champagne. That impression is wrong, and the present attitude of the peasants in the Champagne districts is a striking example of the misjudgment of the public in this matter. The French Government, we suggest, might do well to inaugurate a system of control which shall secure nothing but the bottling of the Champagne-grown product under a Champagne label, and reserve another designation for other wines.

## SAPHENOUS VARIX SIMULATING FEMORAL HERNIA.

IN the *Journal of the American Medical Association* of Dec. 31st, 1910, Dr. A. H. Noehren has reported a remarkable case in which a saphenous varix simulated femoral hernia, and later, as the result of thrombosis, strangulation of the hernia. A woman, aged 37 years, the mother of seven children, of whom the youngest was three years old, complained of crampy pains all over the abdomen, but most severe in the lower part of the left side, with continual rumbling of gas. She had always enjoyed good health and had worked hard all her life. As she had been constipated for a few days she had taken several doses of castor oil, which increased the pain, though they caused a good action of the bowels. The temperature was 98° F., and the pulse was 112. The abdomen was soft and nothing abnormal could be felt in it. Just below the left saphenous opening was a swelling about the size of a walnut. It was not tender, was easily reducible, especially when the patient lay down, and gave a decided impulse on coughing. The patient said that she had noticed this swelling since the birth of her last child, and that it never gave her any trouble. Dr. Noehren diagnosed femoral hernia and recommended operation in view of the danger of strangulation. The pain he attributed to the cathartic. Three days later he was called again. The pains had grown worse, especially on the lower part of the left side, and radiated down the left thigh. Frequent soft stools were passed, and there was marked rumbling of gas. The temperature was 100° F. and the pulse was 124. Peristaltic waves could be seen over the lower left side of the abdomen, which was tender and more resistant than on the right side. The "hernial mass" was a little larger, tender, and no longer reducible. Operation was urgently advised, but was declined. During the day the temperature rose to 102·6°, and an indistinct mass could be felt in the lower left quadrant of the abdomen. On the evening of the next day the bowels acted, but with much difficulty and straining. There was considerable resistance in the lower part of the left side of the abdomen, and the whole abdomen was swollen and tympanitic, especially over the course of the colon. The patient felt nauseated and vomited a little bile. The mass was tense, tender, and dull to percussion. The temperature was 102·2° and the pulse was 124. Operation was now insisted on. An incision was made over the "hernial swelling" sufficient for a radical operation. On dissecting out the mass Dr. Noehren found to his surprise that it did not emanate from the saphenous opening, but was a pouch springing from the anterior wall of the internal saphenous vein just below the saphenous opening. The vein was tied above and below and the mass was removed. On opening it was found to be a dilatation of the vein and to contain unorganised clot. The femoral ring was not unduly large. Nevertheless, Poupart's ligament was sutured to the pectineal fascia to prevent the possibility of a future hernia or the recurrence of one that might have slipped back into the abdomen. The wound was closed with interrupted silkworm gut sutures. Examination now revealed a large infiltrating mass occupying the pouch of Douglas and extending upwards into the left side of the abdomen. It was decided to terminate the operation at this point and await developments. The temperature was irregular for ten days after the operation, after which it suddenly became normal, where it stopped during the following eight days that the patient stayed in hospital. During this time the pelvic mass gradually became smaller and on her discharge could barely be felt. Saphenous varix in the situation described is very rare. According to MacCready's statistics, quoted in Keen's text-book on "Surgery," a saphenous varix, an abscess, and enlarged glands have been mistaken for femoral hernia 9, 47, and 115 times respectively in circumstances that allow comparison. In this connexion we are talking of simple varix, but in the case narrated above the circumstances were different. After three days a tumour with impulse on coughing and easily reducible became no longer reducible and tender, while there were a rising temperature, abdominal pains, a swollen tympanitic abdomen, and the other symptoms mentioned. After the operation the explanation was simple enough. The varix had become thrombosed, and the temperature and abdominal symptoms were due to pelvic exudation.

## RAG FLOCK.

THE representatives of the rag flock trade would be well advised, we think, not to haggle over refinements if they wish to see their manufactures placed on a hygienic basis. There is at present a dissension amongst them; there are those who are in favour of efficient steam sterilisation, while others regard thorough washing coupled with drying by heat as all that is necessary to turn out a clean material. It seems to us that if, as a result of legislation, rag flock used for bedding and upholstery is compelled to undergo a process which is as effectual as the laundry is with soiled linen, the whole business would be freed from reproach. We do not expect our shirts to be completely sterile; we are content if they are clean. It may be suggested, however, that in the laundering process the fabrics are boiled and that thus some amount of sterilisation is effected. While that is probably true, it would not be difficult to insist that washed rag flock should afterwards be dried by heat, a step which, as a matter of fact, is adopted by the manufacturers themselves as a convenient method of finishing off the material. After carefully considering the *pros* and *cons* of the question, it seems to us to be a counsel of perfection to insist upon a degree of sterilisation for rag flock equal to

that required for, say, a surgical dressing. Moreover sterilisation does not necessarily remove filth, and the efficiency of sterilisation cannot be checked in the ready and simple manner that the efficiency of a washing process can. We have known sterilised bedding material to develop an offensive smell after a time, an objectionable quality which would be obviated by efficient washing. It will be a pity if the very desirable legislation on this matter should be delayed by setting up an unnecessary ideal, and on carefully considering both the scientific and economic aspects of the question we think that the majority of those concerned would welcome a Bill from Parliament providing for the cleansing and heat-drying of rag flock on the lines suggested.

## REST IN BED IN ANGINA PECTORIS.

AT a meeting of the Académie de Médecine of Paris on Nov. 29th M. Ch. Fiessinger presented an elaborate study of the effect of rest in bed in angina pectoris due to organic disease (in which the attacks are always produced by exertion). The late M. Huchard has insisted on the value of reducing the blood pressure in angina pectoris, the crises of which are liable to be accompanied by increased blood pressure. M. Fiessinger pointed out that rest in bed not only lowers blood pressure but acts as a tonic to the heart and diminishes its irritability. What part is played by these different factors? In his cases he found four different conditions: 1. The blood pressure during the pain was normal or low and was not modified by rest in bed. 2. The pressure during the attack was raised but was not modified by rest in bed. These two classes formed only a minority of the cases. 3. The pressure was high and was lowered by rest in bed; this held for two-thirds of the cases. 4. In exceptional cases the pressure was not lowered, but even rose, and curiously this was not accompanied by increase of the pain. In the first class three patients were seen. An example was a man, aged 66 years, who had an aortic systolic murmur and showed only slight acceleration of the pulse on walking. An attack of angina pectoris followed the exertion of putting to bed a sick relative. The maximum blood pressure with Pachon's sphygmometer was 17 centimetres of mercury and remained the same after rest in bed, which caused the symptoms to disappear. In the second class three patients in the "sixties" suffering from atheroma with aortic disease were seen. The maximum pressure varied from 24 to 27 and was not modified by rest in bed. Yet the pain was much diminished—a proof that it is not the arterial tension which caused the pain. In the third class 11 patients were seen. Thus a man, aged 64 years, had a maximum pressure of 28 during an attack. Under rest in bed, ice to the præcordium, milk diet, and morphine injections the pressure was reduced to 19. Eight patients showed reduction of pressure of from 2 to 4 centimetres of mercury with great relief. In the fourth class, in which a high blood pressure was not lowered by rest in bed, the effect on the pain was variable; in some cases it was considerably relieved, in others only slightly. M. Fiessinger concludes that the part played by high blood pressure in angina pectoris has been exaggerated, and that this condition no more produces the crises than it does those of biliary colic or puerperal eclampsia. Rest in bed relieves the subjects of angina pectoris, but only partly by its effects on the blood pressure. To give full results rest in bed must be prolonged to six weeks, and even to two months when the patient cannot take a step without provoking pain. A milk diet should be ordered; later, farinaceous food may be added. The usual drugs (theobromine, trinitrine, morphine, and digitalin) are given at the same time. But nothing has such a certain and rapid action as rest in bed. Recourse should be had to it again if after a period of immunity the symptoms recur. The greatest relief is obtained in aged patients or in those who lose flesh during the treatment; the least in patients suffering from concomitant aortic insufficiency.

## TOBACCO SUBSTITUTES FOR CHILDREN.

IF a policeman sees a child in a street or public place smoking a cigarette which proves on inspection to contain tea-leaves or some smokable herb other than tobacco, that child commits an offence under the clauses of the Children Act (1908) dealing with the prohibition of juvenile smoking, for the expression "cigarette" includes cut tobacco rolled up in paper, tobacco leaf, or other material in such form as to be capable of immediate use for smoking. The Act, therefore, does not leave untouched the question of the possibility of tobacco substitutes being as injurious to the child smoker as genuine tobacco. The Act dealing with this part of the subject assumes that not only the smoking of tobacco but of substitutes also is an offence, because all are calculated to injure the health. Nicotine is the substance commonly looked upon as the injurious constituent peculiar to tobacco, but doubt has frequently been expressed as to whether any important amount of the alkaloid is contained in the smoke, and therefore whether nicotine reaches the mouth. Tobacco smoke is a poison apart altogether from the question of its containing nicotine. Amongst other things contained in tobacco smoke are the poisons pyridin and carbon monoxide. The production of carbon monoxide and pyridin are, of course, not peculiar to the smoking or incomplete combustion of tobacco. They are produced in practically all cases where the combustible matter contains carbohydrates and nitrogenous matters. It would be an astonishing fact to find, for instance, in the incomplete combustion of tea-leaves, cane, paper, coltsfoot, or any dried herb that the smoke was free from one or other of these common pyroligneous products, as the chemist calls them. It has come to our knowledge that certain herbal mixtures are made for the express purpose of providing children under 16 years of age with something to smoke, under the idea apparently that the Act applies strictly to tobacco. We can well believe that such mixtures are likely to be just as mischievous as, at any rate, the lighter tobaccos, and if the smoking of these substitutes escapes the vigilance of the police the good intentions of the Children Act may be frustrated. The mixture is clearly sold under a misapprehension on the part of the sellers, as its sale to children should come under the same restrictions as tobacco.

## THE ISOLATION OF EPIDEMIC DISEASES BY THE METROPOLITAN ASYLUMS BOARD IN 1910.

IT is difficult to over-estimate the beneficial effect of the Metropolitan Asylums Board hospitals on the health of London, through the isolation and treatment of epidemic diseases, more especially of scarlet fever, diphtheria, and enteric fever. According to returns furnished to the Registrar-General during the 52 weeks of last year, it appears that 15,053 cases of these three diseases were admitted to the hospitals of this Board—namely, 9682 of scarlet fever, 4698 of diphtheria, and 673 of enteric fever. During the year 10,231 cases of scarlet fever were discharged as recovered, and 206 deaths from this disease occurred in these hospitals; these 206 deaths were equal to 2·0 per cent. of the 10,437 completed cases during the year, and it is interesting to note that in addition to these 206 deaths only eight fatal cases of scarlet fever were registered in London last year (of which two occurred in the London Fever Hospital), and that the 214 total deaths from this disease were considerably less than half the average annual number registered in London during the preceding nine years 1901–09, and were fewer

than in any previous year for which similar information is available. Of diphtheria, 4415 cases were discharged during last year from these isolation hospitals as recovered, and 360 deaths from this disease occurred therein. These 360 deaths from diphtheria were in the proportion of 8·0 per cent. of the 4775 completed cases of this disease. The total deaths from diphtheria registered in London during last year were 434, of which 360, or 83 per cent., occurred in the Metropolitan Asylums hospitals and three in the London Fever Hospital; in the three preceding years the registered deaths from this disease in London were 781, 724, and 605 respectively, showing a steady decline, which was most marked last year. With regard to the isolation of enteric fever, 521 cases of this disease were discharged during last year from these Metropolitan Asylums hospitals as recovered, and 126 deaths therefrom occurred in these hospitals. These 126 deaths showed a proportion of 19·5 per cent of the 647 cases completed during the year. The number of deaths referred to enteric fever in London during the 52 weeks of last year were 198, of which 126, or 64 per cent., occurred in the Metropolitan Asylums hospitals; these 198 deaths were 107 below the average annual number in the nine preceding years 1901–09, but showed an increase of 52 upon the unprecedentedly low number in 1909. With reference to the case-mortality of these three diseases in the Metropolitan Asylums hospitals, it may be noted that the mortality of scarlet fever has shown a marked and continuous decline in recent years, suggesting a considerably milder type of the disease; whereas the case-mortality of diphtheria and of enteric fever have shown no similar steady decline. It is a fact, however, of which the explanation is not obvious, that the case-mortality during last year of both scarlet fever and diphtheria in the Metropolitan Asylums hospitals was considerably higher than among the comparatively small number of cases under treatment in the London Fever Hospital.

## THE DILEMMA OF THE BATTERSEA TOWN COUNCIL.

As will be seen by a note which we publish on p. 279 of our present issue rumblings are still to be heard in Battersea in connexion with the brown dog storm, but the continuance of bad weather predicted by an ex-mayor, who announced that the "memorial would have to be restored by the council before very long," seems likely to be falsified; for an action in the High Court to enforce the contract between members of the International Antivivisection Council and the Mayor, &c., of Battersea with respect to the erection and maintenance of the memorial has resulted in a judgment which enables an alternative weather forecast to be made with confidence. It is, however, unnecessary to devote further space to the matter here. It will be noticed that at the same meeting at which these echoes were heard the subject of supplying the poor of Battersea with diphtheria antitoxin came up for discussion, with the result that the town council, which, be it noted, is the sanitary authority that has charge of the health of the people, postponed for six months the consideration of the opportunities afforded by the recent Order of the Local Government Board which enables diphtheria antitoxin to be supplied and administered gratuitously, though it appears that some of the antivivisectionists and antivaccinationists on the council had misgivings as to whether in the interests of the health of the poor they ought not to take a different view. It would be interesting to know what the intelligent artisans of Battersea think of this act of the council. Although the practice of supplying vaccines and sera through the agency of local authorities is daily increasing, as also is the demand for these substances in relation to numerous diseases, the people of Battersea will be unable to procure them save through private or Poor-law channels. Over and over again have we insisted in these columns upon the enormous importance of the earliest possible employment of the diphtheria antitoxin, and we have drawn attention to the numerous reports of medical officers of health as to the frequency with which diphtheria patients reach the isolation hospital even in advanced disease and no antitoxin has been administered. Our brief report states that two of the medical men on the council were apparently not on the side of the gratuitous supply of antitoxin, and that one of them spoke of the dangers of administering the injection in dirty homes. When the operation is performed carefully this risk cannot be great, not one, we think, that can be considered in any sense commensurate with the dangers of untreated diphtheria.

## A REVIEW OF BACTERIOLOGY AND GENERAL PARASITOLOGY.

OUR contemporary, the *Medical Officer*, is to be congratulated on the new venture which accompanies the first issue of the present year. A supplement to the paper, bearing the title "The Review of Bacteriology, General Parasitology, and Allied Subjects in their Relationship to Pa hology and Hygiene," is henceforth to be published at least once in each month. The numbers of papers which appear annually in contemporary scientific journals at home and abroad render the task of keeping up with recent work a matter of great difficulty. To read the specialist reviews published on the continent, and analyses of recent work in pathology, bacteriology, hygiene, tuberculosis, the *Bulletin* of the Pasteur Institute of Paris, and so on, means the perusal of several large volumes annually and entails a knowledge of the French and German languages at any rate. For this reason a summary of such work concisely worded in the English language should meet with a large measure of success. The *Medical Officer* has been fortunate in securing as editor of its review Mr. A. G. R. Foulerton, and it has been decided to publish the supplements so that they can be bound, if desired, separately from the journal itself. The January Supplement contains reviews of 34 papers. The following subjects are dealt with: tuberculosis (7), leprosy (2), typhoid and paratyphoid fever (3), cholera and diphtheria. The recent work on the bacteriology of cerebro-spinal meningitis, broncho-pneumonia in infants, and non-tuberculous diseases of the lungs is passed in review. Then there is an interesting note of Metchnikoff's observations on the flora of the intestines, and of Wollman's on the action of the small intestine on bacteria. The aerobic and anaerobic bacteria of milk and the preservation of butter receive attention, and the laboratory investigations into the etiology of pleuro-pneumonia of cattle are dealt with. Under the heading of protozoology the review deals with the as yet unfinished works on experimental syphilis in the lower animals and with the recent additions to the study of trypanosomiasis.

THE Rizzoli Institute of Orthopædics, Bologna, announces the award of the Humbert I. Prize in Orthopædics for the second quinquennial period ending Dec. 31st, 1909, to Professor Wilhelm Schulthess of Zürich for the work "Die Pathologie und Therapie der Rückgratsverkrümmungen" (Jena: Fischer, 1906). The judges were Professor A. Codivilla of Bologna, Professor G. Kirmisson of Paris, and Professor O. Vulpius of Heidelberg.

THE Lettsomian lectures on "A Review of the Operations for Stone in the Male Bladder" will be delivered by Mr. William Frederick Haslam on Feb. 6th and 20th, and March 6th, at 9 P.M., at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W.

# KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE report of the meeting of the Governors and Council of King Edward's Hospital Fund for London, which was held on Dec. 14th at St. James's Palace under the Presidency of the Duke of TECK, will be found on pp. 1852–53 of THE LANCET, Dec. 24th, 1910. The following is a list of the grants recommended by the Distribution Committee. (*Note*—The absence of a grant does not necessarily imply dissatisfaction.)

Alexandra Hospital for Children, £400.
Beckenham Cottage Hospital, £50, £25 of which to renewal of floors.
Belgrave Hospital, £1000, to reduce building debt.
Blackheath and Charlton Cottage Hospital, £100.
Bolingbroke Hospital, £1500.
British Lying-in Hospital, £400.
Catholic Nursing Institute. No grant.
Central London Ophthalmic Hospital, £1000, to rebuilding in accordance with scheme submitted to the Fund.
*Central London Throat and Ear Hospital.
Charing Cross Hospital, £3000.
Chelsea Hospital for Women, £750.
Cheyne Hospital. No grant.
City of London Hospital for Diseases of the Chest, Victoria-park, £4000.
City of London Lying-in Hospital, £500.
Clapham Maternity Hospital, £200.
Dreadnought Hospital, £4000, £1000 of which to reduce debt.
Ealing Cottage Hospital, £500, to rebuilding in accordance with scheme submitted to the Fund.
East End Mothers' Lying-in Home, £500, £250 of which to reduce debt.
East London Hospital for Children, £2000, £250 of which to improvements.
Eltham and Mottingham Cottage Hospital, £100.
Evelina Hospital, £150.
French Hospital, £200.
Friedenheim Hospital, £50.
General Lying-in Hospital, £250.
German Hospital, £200.
Gordon Hospital for Fistula, &c., £25.
Great Northern Central Hospital, £4000, £1000 of which to reduce debt.
Grosvenor Hospital for Women, £350.
Guy's Hospital, £7500, £1500 of which to building improvements in accordance with scheme submitted to the Fund.
Hampstead General Hospital, £3150, £1500 of which to reduce debt and £1650 on account of maintenance and rent, as agreed upon amalgamation with North-West London Hospital.
Home and Infirmary for Sick Children, £250, £50 of which to outside staircase.
Home for Mothers and Babies, Woolwich, £100.
Hospital and Home for Incurable Children, Hampstead, £100, £75 of which to improvements.
Hospital for Consumption, Brompton (including Sanatorium at Frimley), £3000.
*Hospital for Diseases of the Throat.
Hospital for Epilepsy and Paralysis, £750.
Hospital for Invalid Gentlewomen, £200.
Hospital for Sick Children, £4000, £1500 of which to recent improvements in accordance with scheme submitted to the Fund.
Hospital for Women, Soho square, £1000.
Hospital of St. John and St. Elizabeth, £350.
Infants Hospital, £25.
Italian Hospital, £500.
Kensington and Fulham General Hospital (late Queen's Jubilee Hospital). No grant.
Kensington Dispensary and Children's Hospital, £25.
King's College Hospital, £7000, £5000 of which to removal fund.
Leyton, Walthamstow, and Wanstead Children's and General Hospital, £250.
London Fever Hospital, £250.
London Homœopathic Hospital, £500, to rebuilding of Nursing Home in accordance with scheme submitted to the Fund.
London Hospital, £12,000.
London Lock Hospital, £1500, to the Harrow Road Hospital, £1000 of which to reduce debt.
London Temperance Hospital, £1500.
*London Throat Hospital.
Maternity Charity and District Nurses' Home, Plaistow, £100.
Medical Mission Hospital, Balaam-street, Plaistow, £35.
Memorial Hospital, Mildmay Park, £50.
Metropolitan Hospital, £3500, £1000 of which to reduce debt on structural improvements carried out in accordance with scheme submitted to the Fund.
Middlesex Hospital, £4000.
Middlesex Hospital Cancer Charity. No grant. The Committee are glad to see that no assistance from the Fund is required this year.
Mildmay Mission Hospital, £400.
Miller General Hospital for South-East London, £1500, £750 of which to extension, subject to scheme being approved.
Mount Vernon Hospital for Consumption (including Sanatorium at Northwood), £1500.
National Anti-Vivisection Hospital. No grant.
National Dental Hospital, £400, £150 of which to improvements in accordance with scheme submitted to the Fund.
National Hospital for Diseases of the Heart. No grant.
National Hospital for the Paralysed and Epileptic, £1000.
New Hospital for Women, £1500, £750 of which to building improvements in accordance with scheme submitted to the Fund.
Norwood Cottage Hospital, £100.
Paddington Green Children's Hospital, £1750, £1000 of which to reconstruction of Out-patient Department, subject to approval of scheme.
Passmore Edwards Acton Cottage Hospital, £75.
Passmore Edwards East Ham Hospital, £50.
Passmore Edwards Hospital for Willesden, £25.
Passmore Edwards Cottage Hospital, Wood Green, £25.
Poplar Hospital, £400.
Prince of Wales's General Hospital, £4000, £2000 of which to reduce debt.
Queen Charlotte's Lying-in Hospital, £1500, £500 of which to improvements.
Queen's Hospital for Children, £3000, £1250 of which to reduce building debt.
Royal Dental Hospital of London, £1250, £250 of which to recent improvements.
*Royal Ear Hospital.
Royal Eye Hospital, £1000, £250 of which to reduce debt.
Royal Free Hospital, £4000.
Royal Hospital for Diseases of the Chest, City-road, £1250, £250 of which to reduce debt.
Royal Hospital, Richmond, £200, £50 of which to fire-escape balconies.
Royal London Ophthalmic Hospital, £2500.
Royal National Orthopædic Hospital, £7000, £250 of which as agreed upon amalgamation.
Royal Waterloo Hospital for Children and Women, £1500.
St. George's Hospital, £2000. To be retained until the Fund is satisfied that the relations between hospital and medical school are in accordance with the principles intimated by the Fund in March, 1909
St. John's Hospital for Diseases of the Skin, £600, £500 of which to reduce building debt.
St. John's Hospital, Lewisham, £300.
St. Luke's House, £50.
St. Mark's Hospital, £400, £300 of which to improvements in nursing accommodation in accordance with scheme submitted to the Fund.
St. Mary's Hospital, £6500, of which £2500 to reduce debt.
St. Mary's Hospital for Women and Children, Plaistow, £1500, £1000 of which to enable the new building to be furnished and opened free of debt.
St. Monica's Hospital, £100.
St. Peter's Hospital for Stone, £150.
St. Saviour's Hospital, Osnaburgh-street, £200.
St. Vincent's Home for Crippled Boys. No grant.
Samaritan Free Hospital, £1000.
Santa Claus Home, £25.
South Wimbledon, Merton and District Cottage Hospital, £1000, to the rebuilding of the hospital under the name of the Wimbledon and Merton Hospital, in accordance with scheme submitted to the Fund.
University College Hospital, £5500, £1500 of which to reduce debt.
Victoria Hospital for Children, £1000.
West-End Hospital for Diseases of the Nervous System, £250.
Western Ophthalmic Hospital, £275, to reduction of debt on rebuilding of out-patient department.
West Ham and East London Hospital, £5500, £5000 of which to building fund to enable the new building to be opened free of debt.
West London Hospital, £5000, £2000 of which to reduce debt, on the understanding that special efforts are made to obtain increased support from the public.
Westminster Hospital, £3000.
Wimbledon Cottage Hospital, £550, £500 of which to rebuilding in accordance with scheme submitted to the Fund.
Total of grants to hospitals for the year 1910, including £2000 set aside for amalgamation of throat and ear hospitals, £150,000.

The grants recommended by the Convalescent Homes Committee are as follows:—

### *Consumption Sanatoriums.*

Children's Sanatorium, Holt, Norfolk. No grant. The Committee are glad to see that the balance of the building fund for a permanent sanatorium has been provided by a private donor.
Devon and Cornwall Sanatorium, Didworthy, South Brent, £875, in consideration of the reservation of ten beds during 1911 for the use of certain London hospitals.
Fairlight Sanatorium, Hastings. No grant.
Kelling Sanatorium, Holt, Norfolk, £175, in consideration of the reservation of two beds during 1911 for the use of certain London hospitals.
Maitland Sanatorium, Peppard, Oxon. No grant.
National Association for the Establishment and Maintenance of Sanatoria for Workers, Benenden, Kent, £250 to reduce building debt.
Northampton Sanatorium, Creaton, Northants, £525, in consideration of the reservation of six beds during 1911 for the use of certain London hospitals.
Royal National Hospital for Consumption, Ventnor. No grant.
Total of grants to consumption sanatoriums, £1825.

### *Convalescent Homes.*

Alexandra Hospital for Children, Painswick, £25.
All Saints' Convalescent Home for Children, Highgate, £25.
Baldwin Brown Home for Convalescent Poor, Herne Bay, £25.
Brentwood Convalescent Home for London Children, Brentwood, £25.
Charing Cross Hospital, Limpsfield, £200, £100 of which to reduce debt and £100 maintenance grant with a view to encouraging the admission without payment of patients direct from the hospital.
Chelsea Hospital for Women, St. Leonards, £50, with a view to encouraging the admission without payment of patients direct from the hospital.
Children's Cottage Hospital, Cold Ash, Newbury, £25, in consideration of convalescent cases.
Children's Home Hospital, Barnet, £25, in consideration of convalescent cases.
Convalescent Police Seaside Home, Hove, £50.
Deptford Medical Mission, Bexhill, £25.
East London Hospital for Children, Bognor, £250.
Erskine House, Hampstead Heath, £25.
Great Northern Central Hospital, Clacton-on-Sea, £100.

Home and Infirmary for Sick Children, Sydenham, Broadstairs, £50.
Hospital for Sick Children, Great Ormond-street, Highgate, £225.
King's College Hospital, Hemel Hempstead, £100.
London Hospital, Tankerton, £50.
Mary Wardell Convalescent Home for Scarlet Fever, Stanmore, £25.
Metropolitan Convalescent Institution (Children), Broadstairs, £150.
Metropolitan Convalescent Institution, Walton, £200.
Metropolitan Hospital, Cranbrook, £50.
Middlesex Hospital, Clacton, £400.
Mildmay Mission Hospital, Hendon, £100.
Mrs. Kitto's Free Convalescent Home, Reigate, £50.
National Hospital for the Paralysed, Finchley, £100, with a view to facilitating the admission of patients without payment.
Paddington Green Children's Hospital, Slough, £100.
Poplar Hospital, Walton-on-Naze, £50.
Queen Charlotte's Lying-in Hospital, Kilburn, £50.
St. Andrew's Convalescent Home, Folkestone, £100.
St. Andrew's Convalescent Hospital, Clewer, £50.
St. Mary's Home for Children, Broadstairs, £50, in consideration of convalescent cases.
St. Michael's Home for Men and Women, Westgate-on-Sea, £25.
Sunshine Home of Recovery, Hurstpierpoint, £25.
Surgical Home for Boys, Banstead, £25.
Victoria Home for Invalid Children, Margate, £100 to building, in consideration of convalescent cases.
Victoria Hospital for Children, Chelsea, Broadstairs, £225.
Winifred House Invalid Children's Convalescent Hospital Home, Tollington Park, £25.
Total of grants to convalescent homes, £3175.

* With regard to the throat, nose, and ear hospitals, the committee recommend that the policy of setting aside grants towards amalgamation in place of separate awards to any of the four institutions concerned should still be continued, and they have voted £2000 this year to this purpose.

## BRITISH MEDICAL BENEVOLENT FUND.

AT the December meeting of the committee 27 cases were considered and grants amounting to £220 made to 25 of the applicants. Appended is an abstract of the cases relieved.

L.S.A., aged 60 years. Is temporarily incapacitated, and when helped earlier in the year was given leave to apply again in six months' time. Relieved once, £10. Voted £5.

M.R.C.S., L.R.C.P., aged 42 years. Is in ill-health and dependent on help from friends. Wife gives music lessons. One child, aged 8. Voted £5.

M.R.C.S., L.R.C.P., aged 47 years. Quite incapacitated and dependent on friends. No children. Voted £10.

Widow, aged 50 years, of M.R.C.S., L.S.A. Unprovided for at death of husband six months ago and has been obliged to give up a post as companion on account of a nervous breakdown. No children. Voted £5.

Widow, aged 61 years, of M.R.C.S., L.S.A. Husband's savings were exhausted by a three years' illness preceding death, and applicant endeavours to support herself by taking boarders. Seven children, but one an invalid and the others only just self-supporting. Voted £12.

Widow, aged 53 years, of L.R.C.P., L.R.C.S. Edin. No income; no children; lets lodgings. Voted £5.

Widow, aged 64 years, of M.R.C.S., L.S.A. Lost her husband a few months ago after a long illness and is endeavouring to obtain resident patients or paying guests. Voted £6.

Daughter, aged 55 years, of late M.D. Aberd. Has supported herself until recently, but is now broken down in health. Voted £10.

Widow, aged 70 years, of M.R.C.S., L.R.C.P. Slight provision made by husband has to be supplemented by gifts from friends and is quite inadequate for present unavoidable expenses due to illness. Voted £5.

Widow, aged 59 years, of M.R.C.S., L.S.A. No income and has exhausted the proceeds of the sale of her furniture. Health very feeble. Relieved once, £16. Voted £10.

Widow, aged 75 years, of M.R.C.S. Dependent on an Old Age Pension and occasional gifts from friends. Relieved twice, £24. Voted £12.

Widow, aged 69 years, of M.R.C.S. No income and dependent for a home on a son-in-law, who can ill afford to assist. Relieved once, £10. Voted £10.

Widow, aged 49 years, of M.R.C.S. Husband's means exhausted by a long illness ending in death, and applicant is endeavouring to establish a boarding-house. Relieved once, £10. Voted £10.

Widow, aged 52 years, of M.R.C.S. Nursed her husband for several years before his death, and is now herself incapacitated and a candidate for a pension from a Home for Incurables. Dependent on two sons whose earnings are very small. Relieved seven times, £92. Voted £10.

Widow, aged 51 years, of L.S.A. No income and health too uncertain to attempt regular employment. Two daughters, aged 18 and 16, the latter having just obtained a post as governess. Relieved five times, £46. Voted £12.

Widow, aged 66 years, of L.R.C.P. Only income a few shillings a week from a house, if let. No children. Relieved 11 times, £126. Voted £12.

Widow, aged 75 years, of M.D. Glasg. Endeavours to support herself by taking lodgers, but is unable to pay her rent which is considerably overdue. Relieved seven times, £36. Voted £5.

Daughter, aged 64 years, of late M.D. Edin. Has supported herself for many years as a companion, but is now dependent on this Fund and another charitable society. Relieved six times, £72. Voted £12.

Daughter, aged 70 years, of late L.R.C.S., L.S.A. Takes boarders but finds it impossible to make both ends meet and is in arrears with her rent. Relieved three times, £20. Voted £10.

Widow, aged 54 years, of L.R.C.P., L.R.C.S. Edin. No income and is in very bad health. Children only able to give slight help. Relieved four times, £48. Voted £12.

Widow, aged 66 years, of M.R.C.S. Receives a pension from Epsom College and requires a little help in consequence of the unavoidable withdrawal of assistance by friends. Relieved six times, £54. Voted £10.

Widow, aged 65 years, of M.R.C.S. Dependent on the help of two relations and small profits from a boarder, if able to obtain one. No children. Relieved once, £6. Voted £6.

Widow, aged 65 years, of L.R.C.P., L.R.C.S. Edin. Has supported herself since husband's death several years ago, but is now crippled by rheumatoid arthritis and dependent on a sister who is a teacher. Relieved once, £12. Voted £12.

Daughter, aged 63 years, of late M.D. Edin. Gave up a post as companion to nurse an elder sister who is a permanent invalid and is dependent on this Fund and a small yearly grant from an old friend. Relieved five times, £60. Voted £12.

Daughter, aged 40 years, of late F.R.C.S. No income and unable to follow any regular occupation on account of ill-health. Relieved ten times, £96. Voted £2 and case to be reconsidered in a month's time.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W.

# Looking Back.

FROM

## THE LANCET, *SATURDAY*, Jan. 26th, 1833.

### ARTIFICIAL MODE OF INDUCING PARTURITION.

IN the annual statements just published by Professor Ciniselli of Pavia, regarding the clinical events in the obstetric establishment of that university, there is a case of artificial delivery at the eighth month, successfully induced by the introduction of a sponge dilator into the mouth of the uterus. The sponge first employed was about an inch long, and the thickness of a quill. When its increase of size had dilated the orifice to a certain extent, another, a little larger, was substituted for the first, and with the same effect. In the course of forty-eight hours four sponges were employed, when the delivery was accomplished by the natural contractions of the uterus, and with safety to mother and child.

PERSIAN OPIUM.—Dr. EPPS has sent to our office a specimen of a new kind of opium, adding a fifth,—the Persian,—to the four which we already possess, the Turkey, the East Indian, the Egyptian, and the European. "It has been imported into this country," he observes, "only very lately, and the specimen is one of the first parcel imported. It comes from Trebizond, in Persia, and was obtained from Messrs. Yeatman and Linn, chemists, of Fore-street, City. It is in small cylindrical pieces, rolled in polished paper, at one end closed with cotton, at the other partially open. Its colour is *reddish-brown*, and in this character it approaches to the best opium, though much lighter in colour than the Turkey. It has a very fetid, heavy smell, and a bitter, acrid taste. It would appear from its sensible qualities to be very valuable and active, and, it is to be remembered, that a great part of the 'Turkey opium,' as it is called, comes from Persia."

## VITAL STATISTICS.

### VITAL STATISTICS FOR 1910.

THE following are the provisional figures showing the birth-rates and death-rates in England and Wales in the year 1910:—

| — | Annual rates per 1000 living. | | | | Deaths under one year to 1000 births. |
|---|---|---|---|---|---|
| | Births. | Deaths. | | Principal epidemic diseases. | |
| | | Crude. | Corrected.* | | |
| England and Wales | 24·8 | 13·4 | 13·4 | 0·99 | 106 |
| 77 great towns ... | 25·0 | 13·4 | 14·3 | 1·23 | 115 |
| 136 smaller towns | 23·7 | 12·4 | 12·9 | 0·88 | 104 |
| England and Wales less the 213 towns | 25·0 | 13·6 | 12·8 | 0·74 | 96 |

* The corrected death-rates are the rates which would have been recorded had the age and sex constitution of the populations of the several areas been identical with that of England and Wales as enumerated in 1901.

### HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8374 births and 5411 deaths were registered during the week ending Jan. 21st. The annual rate of mortality in these towns, which had been equal to 14·3 and 15·5 per 1000 in the two preceding weeks, further rose to 16·4 in the week under notice. During the first three weeks of the current quarter the death-rate in these towns averaged 15·4 per 1000. In London

the mean death-rate during the same period was equal to 15 5. The annual death-rates in the 77 towns during last week ranged from 7·1 in King's Norton, 7·7 in Handsworth, 9·3 in West Hartlepool, and 9 9 in Gateshead, to 21·0 in Bury, 21·4 in Coventry, 23·0 in Middlesbrough, and 25·1 in Stockton on-Tees. The 5411 deaths from all causes in the 77 towns last week showed a further increase of 308 on the numbers returned in the three preceding weeks, and included 455 which were referred to the principal epidemic diseases, against 392 and 448 in the two preceding weeks; of these 455 deaths from epidemic diseases, 204 resulted from measles, 85 from whooping-cough, 68 (of infants under two years of age) from diarrhœa and enteritis, 63 from diphtheria, 20 from scarlet fever, and 15 from enteric fever, but not one from small-pox. The fatal cases of measles, which had been 160 and 191 in the two preceding weeks, further rose last week to 204, and caused the highest annual rates, 1 9 in Tottenham, Coventry, and Middlesbrough, 2·2 in Oldham, and 2·6 in Sheffield. The 85 deaths from whooping-cough were within two of the number in the previous week, and caused rates equal to 1·1 in Leyton, and 1·2 in Willesden, in Reading, and in York. The 68 deaths of infants under two years from diarrhœa and enteritis showed an increase of 12 upon the number returned in the previous week. The fatal cases of diphtheria, which had been 76 and 63 in the two previous weeks, were again 63 last week, of which 20 occurred in London and its suburban districts, 4 in Birmingham, 5 in Manchester and Salford, and 3 each in Portsmouth, Leeds, Cardiff, and Swansea The 20 fatal cases of scarlet fever showed a decline of 11 from the number in the previous week; they included 5 in London, 4 in Liverpool, and 3 in Stoke-on-Trent. The deaths referred to enteric fever, which had been 24 and 20 in the two preceding weeks, further declined last week to 15; 2 each were returned in London, Stoke-on-Trent, and Liverpool. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily declined in the ten preceding weeks from 1882 to 1410, had further fallen to 1349 on Saturday last; 126 new cases of this disease were admitted to these hospitals during the week, against 154 and 135 in the two preceding weeks. These hospitals also contained on Saturday last 834 cases of diphtheria, 271 of measles, 118 of whooping-cough, and 72 of enteric fever. The 1613 deaths from all causes in London last week (showing a further increase of 177 upon recent weekly numbers) included 366 which were referred to diseases of the respiratory system, against 263, 289, and 292 in the three preceding weeks. In the 77 towns 169 deaths resulted from different forms of violence, against 180 in each of the two previous weeks; and 433 inquest cases were registered. The causes of 37, or 0·7 per cent., of the deaths registered during the week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Stoke-on-Trent, Salford, and in 51 other smaller towns; the 37 uncertified causes of death in the 77 towns last week included 9 in Liverpool, 5 in Birmingham, 3 in Barrow-in-Furness, and 2 each in Reading, Rochdale, Burnley, Sheffield, and South Shields.

### HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 836 births and 544 deaths were registered during the week ending Jan. 21st. The annual rate of mortality in these towns, which had been equal to 14·3 and 16 6 per 1000 in the two previous weeks, declined again to 14·8 in the week under notice. During the first three weeks of the current quarter the death-rate in these towns averaged 15·2 per 1000, and was 0·2 below the mean rate during the same period in the 77 English towns. The annual death-rates during last week in the eight Scotch towns ranged from 11·1 and 11·5 in Perth and Paisley to 17·6 in Greenock and 17·7 in Dundee. The 544 deaths from all causes in the eight towns last week showed a decline of 67 from the number returned in the previous week, and included 43 which were referred to the principal epidemic diseases, against 56 and 51 in the two previous weeks; these 43 deaths were equal to an annual rate of 1·2 per 1000, the highest epidemic rates being 1·5 in Glasgow and 3·6 in Leith. Of these 43 deaths from the principal epidemic diseases, 20 resulted from whooping-cough, 13 from diarrhœa, 6 from diphtheria, and 2 each from scarlet fever and enteric fever, but not one either from measles or from small-pox. The fatal cases of whooping-cough, which had been 20 and 18 in the two previous weeks, increased again to 20 last week, of which 12 occurred in Glasgow, 4 in Leith, and 2 in Edinburgh. The 13 deaths attributed to diarrhœa corresponded with the number in the previous week, and included 10 of infants under two years of age; 6 deaths from this cause occurred in Glasgow, and 2 both in Dundee and Leith. The deaths referred to diphtheria, which had been 14 and 9 in the two previous weeks, further declined to 6 last week, of which 4 were returned in Glasgow and 2 in Dundee. The 2 fatal cases of scarlet fever and the 2 deaths referred to enteric fever all occurred in Glasgow; the fatal cases of scarlet fever showed a further decline from the numbers in recent weeks. The deaths in the eight towns referred to diseases of the respiratory system, which had been 92, 98, and 130 in the three preceding weeks, declined again to 121 last week, but exceeded by 20 the number in the corresponding week of last year. The deaths resulting from different forms of violence in the eight towns declined to 15 last week, from 19 and 26 in the two previous weeks; and 161, or 30 per cent., of the deaths occurred in public institutions. The causes of 15, or 2·8 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 largest English towns the proportion of uncertified causes of death last week did not exceed 0·7 per cent.

### HEALTH OF IRISH TOWNS.

In Dublin 238 births and 183 deaths were registered during the week ending Jan. 21st. The annual rate of mortality in the city, which had been equal to 21·5 and 21·4 per 1000 in the two preceding weeks, increased to 23 4 in the week under notice. During the first three weeks of the current quarter the annual death-rate in the city averaged 22·1 per 1000, whereas in London the mean death-rate during the same period did not exceed 15·5 per 1000. The 183 deaths from all causes in Dublin last week showed an increase of 16 upon the number in the previous week, and included 18 which were referred to the principal epidemic diseases, of which 6 resulted from whooping-cough, 5 from measles, 4 from diphtheria, and 3 (of infants aged under two years) from diarrhœa and enteritis, but not one from small-pox, scarlet fever, or enteric fever. The fatal cases of whooping-cough, measles, and diphtheria somewhat exceeded the numbers in the previous week. The deaths from all causes included 36 of infants under one year of age, and 43 of persons aged upwards of 65 years; 70, or 38 per cent., of the deaths were recorded in public institutions. The causes of 7, or 3 8 per cent., of the deaths in the city during the week were not certified either by a registered medical practitioner or by a coroner. In Belfast 233 births and 118 deaths were registered during last week. The 118 deaths in this city were equal to an annual rate of 15·4 per 1000, against 16·0 and 19·8 in the two preceding weeks. During the first three weeks of the current quarter the annual death-rate in Belfast averaged 17 1 per 1000, against 22·1 in Dublin during the same period. The 118 deaths from all causes in this city during last week showed a decline of 33 from the number in the previous week, and included 4 which were referred to the principal epidemic diseases, of which 1 each resulted from measles, scarlet fever, whooping-cough, and diphtheria; no fatal case of enteric fever, diarrhœa, or small-pox was registered. One death was referred to violence and 2 were registered on the information of the coroner; 27, or 23 per cent., of the deaths occurred in public institutions. The causes of all but one of the 118 deaths in the city last week were duly certified either by a registered medical practitioner or by the coroner.

### VITAL STATISTICS OF LONDON DURING DECEMBER, 1910.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 4·3 per 1000 of the population, estimated at 4,872,702 persons in the middle of last year. In the three preceding months the rates

* Including membranous croup.

† The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

were 5·3, 5·9, and 5·0 per 1000 respectively. The lowest rates last month were recorded in Paddington, Kensington, Chelsea, the City of Westminster, Hampstead, and Greenwich; and the highest rates in Hackney, Finsbury, the City of London, Bethnal Green, Stepney, Poplar, Bermondsey, and Woolwich. Scarlet fever again showed a declining prevalence last month; among the several metropolitan boroughs the greatest proportional prevalence of this disease was recorded in St. Marylebone, Hackney, the City of London, Poplar, Bermondsey, Camberwell, Lewisham, and Woolwich. The Metropolitan Asylums Hospitals contained 1574 scarlet fever patients at the end of December, against 1825 and 1727 at the end of the two preceding months; the weekly admissions averaged 155, against 229, and 183 in the two preceding months. Diphtheria also was less prevalent than it had been in any of the three preceding months; this disease was proportionally most prevalent last month in Finsbury, Hammersmith, Islington, Bethnal Green, and Bermondsey. There were 827 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 852 and 866 at the end of the two preceding months; the weekly admissions averaged 95, against 120 and 106 in the two preceding months. The prevalence of enteric fever showed a slight decline from that recorded in the preceding month; among the several metropolitan boroughs the greatest proportional prevalence of this disease was recorded in Paddington, Hammersmith, St. Pancras, Hackney, Holborn, Bethnal Green, Poplar, and Camberwell. The number of enteric fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 169 and 134 at the end of the two preceding months, had declined to 88 at the end of last month; the weekly admissions averaged 11, against 25 and 16 in the two preceding months. Erysipelas was proportionally most prevalent in the City of London, Holborn, Finsbury, Bethnal Green, and Stepney. The 27 cases of puerperal fever notified during the month included 4 in St. Pancras, 3 in Lambeth, 3 in Battersea, and 2 each in Islington, Stoke Newington, Finsbury, and Stepney. The 7 cases of cerebro-spinal meningitis included 2 in Wandsworth, and 1 each in St. Pancras, Islington, Hackney, Shoreditch, and Lambeth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates are further corrected for variations in the sex and age constitution of the populations. During the four weeks ending Dec. 31st the deaths of 5592 persons belonging to London were registered, equal to a corrected annual rate of 15·8 per 1000, the rates in the three preceding months having been 11·9, 12·6, and 17·4 respectively. The death-rates last month ranged from 11·7 in Fulham, 11·9 in Greenwich, 12·6 in Lewisham, and 12·9 in Stoke Newington and in Deptford, to 18·0 in Bethnal Green, 19·8 in Holborn and in Bermondsey, 19·9 in Southwark, 20·6 in Shoreditch, and 23·0 in Finsbury. The 5592 deaths from all causes included 532 which were attributed to the principal infectious diseases; of these, 322 resulted from measles, 6 from scarlet fever, 56 from diphtheria, 55 from whooping-cough, 18 from enteric fever, and 75 from diarrhœa. No death from any of these infectious diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Chelsea, City of Westminster, Deptford, Greenwich, Lewisham, and Woolwich; and the highest rates in Hammersmith, Islington, Finsbury, Southwark, and Bermondsey. The 322 deaths from measles were 187 in excess of the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Kensington, Hammersmith, Islington, Finsbury, Southwark, Bermondsey, Lambeth, and Battersea. The fatal cases of scarlet fever numbered 6 last month, the average number being 49; of these 6 deaths, 2 belonged to Poplar, and 1 each to St. Pancras, Islington, Wandsworth, and Greenwich. The 56 deaths from diphtheria were 8 fewer than the corrected average number; the greatest proportional mortality from this disease was recorded in Hammersmith, St. Pancras, Finsbury, Bethnal Green, and Southwark. The 55 fatal cases of whooping-cough showed a decline of 30 from the corrected average number; this disease was proportionally most fatal in Paddington, Kensington, Hampstead, Finsbury, Shoreditch, and Bermondsey. The 18 deaths from enteric fever were 2 below the average for the corresponding period of the five preceding years; these 18 deaths included 3 belonging to Bethnal Green, 3 to Lambeth, and 2 each to Islington, Hackney, and Camberwell. The 75 fatal cases of diarrhœa were 20 in excess of the corrected average number; this disease was proportionally most fatal in Hammersmith, St. Marylebone, Finsbury, Shoreditch, Poplar, and Woolwich. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was 30·9 per cent. above the average.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: E. H. Meaden to the *Orontes;* F. Fedarb to the *Hecla;* and N. L. Richards to the *Mars.* Staff-Surgeon: A. J. Hewitt to the *Blake.* Surgeon: A. S. Paterson to the *Jupiter*, additional.

### ROYAL ARMY MEDICAL CORPS.

Colonel S. C. B. Robinson, from Jubbulpore, has taken over duty as Principal Medical Officer of the First (Peshawar) Division. Lieutenant-Colonel R. R. H. Moore has been transferred from the Southern Command to the Irish Command and appointed Administrative Medical Officer at Belfast in succession to Lieutenant-Colonel E. J. R. Risk. Lieutenant-Colonel A. E. Tate, from Kasauli, has taken over command of the station hospital at Ambala Cantonment. Lieutenant-Colonel T. E. Noding, in charge of the Military Hospital at Cork, has been placed under orders for duty in the Southern Command, joining about March 1st next. Major J. H. Campbell, D.S.O., on arrival home from Mauritius, has been appointed to the London District. Major G. H. Goddard, from Alderney, has been posted to the Eastern Command and appointed medical officer in charge of the Military Families Hospital at Shorncliffe. Major W. W. O. Beveridge, D.S.O., on completion of the tenure of his appointment as medical officer in charge of the Royal Army Clothing Factory at Pimlico, has been appointed Specialist in Sanitation, London District, for duty in connexion with food inspection and analysis. Major W. J. Taylor, at present serving at Holywood, has been placed under orders to embark for service in Sierra Leone. Major G. A. T. Bray, from Southampton, has taken up duty at Maidstone. Captain W. D. C. Kelly has succeeded Captain J. W. West as Specialist in Advanced Operative Surgery, Dublin District, on the latter's departure for India. Captain J. W. Langstaff has been granted four weeks' leave of absence. Captain R. N. Hunt, from Borden, has been placed under orders for duty in Egypt. Captain H. W. Farebrother, from Malapuram, Madras Presidency, has taken up duty at Bangalore. Captain J. P. Lynch, on completion of a tour of service in India, has been posted to the Eastern Command. Captain E. J. Elliot, on return from Tientsin, North China, has been posted to the Northern Command. Captain P. J. Marett has arrived home on leave from Malta. Captain B. S. Bartlett, from Colchester, has been appointed to the station hospital at Multan for duty. Captain A. M. MacLaughlin, sanitary officer of the Scottish Command, has been appointed to officiate as Medical Inspector of Recruits during the absence on leave of Lieutenant-Colonel M. T. Yarr. Captain S. M. Adye-Curran and Captain J. G. Foster have embarked for a tour of service in India. Captain T. S. Coates has been transferred from Queenstown to Woolwich. Captain G. E. Cathcart, from Lancaster, has taken up duty at Warrington. Captain D. C. O'Grady has been appointed specialist in dermatology and venereal diseases to the Second (Rawalpindi) Division. Lieutenant J. B. Jones from Londonderry, has on arrival in India been posted to the station hospital at Lucknow. Lieutenant S. McK. Saunders, from Woolwich, has joined for duty at Cairo. Lieutenant W. W. Treves and Lieutenant R. F. Bridges have been posted to the Eastern Command. Lieutenant C. K. H. Harold has been appointed for duty in the London District from the Aldershot Command.

### INDIAN MEDICAL SERVICE.

Colonel F. C. Reeves has been appointed by the Commander-in-Chief in India to be Principal Medical Officer of the Secunderabad Brigade, in succession to Colonel H. St. Clair Carruthers, transferred to the Civil Medical Department. Lieutenant-Colonel E. W. Thurston, Bombay Presidency, has arrived home on leave. Lieutenant-Colonel F. J. Drury, Principal of the Medical College at Calcutta, has been deputed for special duty with the Principal Medical Officer of the Eighth (Lucknow) Division. Lieutenant-Colonel E. R. W. C. Carroll has taken up duty as Civil Surgeon at Lakhimpur, Eastern Bengal, in succession to Major A. Leventon, appointed civil surgeon at Darrang. Major W. D. Hayward, civil surgeon at Jaipajuri, has been appointed Medical Storekeeper to the Government of India, vice Lieutenant-Colonel E. Dobson. Major E. H. Sharman, on return from leave, has taken over duty as staff officer for Medical Mobilisation Stores Fourth (Quetta) Division from Lieutenant-Colonel C. M. C. Wimberly. Major S. Evans has been selected to officiate as Obstetric Physician to the Parsi Hospital at Bombay. Major M. Dick, civil surgeon, Burma, has been appointed to officiate as a First-class Civil Surgeon. The Governor of Bombay has appointed Major T. S. Novis to act as Professor of Anatomy and Curator of the Museum, Grant Medical College, Bombay, vice Captain L. P. Stephen, pending further orders. Captain S. B. Mehta, district plague medical officer, Lyallpur, has been transferred to Rohtak. The services of Captain R. A. Chambers have been replaced at the disposal of the Home Department of the Government of India. Captain G. Fowler, civil surgeon of Akola, has been appoined to the executive and medical charge of the Akola District Jail. Captain A. H. Proctor, Captain H. Falk, and Captain K. W. Mackenzie have embarked for India in the transport ss. *Rewa* from Southampton. Lieutenant L. H. L. Mackenzie has been attached as medical officer to the 72nd Punjabis at Dera Ismail Khan. Lieutenant A. C. Munro has taken over duty as Specialist in Ophthalmology to the Seventh (Meerut) Division.

### TERRITORIAL FORCE.

*Royal Army Medical Corps.*

3rd Northumbrian Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be Captains: Lieutenant Oswald L. Appleton (dated August 9th, 1910). Lieutenant Percy R. Ash (dated August 19th, 1910).

*Attached to Units other than Medical Units.*—Captain John Paton resigns his commission (dated Jan. 21st, 1911).

### DEATHS IN THE SERVICES.

Colonel J. A. Cunningham, I.M.S. (on Dec. 31st, 1910), who was only recently appointed Inspector-General of Civil Hospitals in the Central Provinces. He was appointed surgeon in 1881 and lieutenant-colonel in 1901. Colonel Cunningham arrived at Calcutta from Nagpur on Dec. 24th for the Christmas holidays, and was seized with cholera two days later, the disease being probably contracted on the railway journey. He failed to rally, and his death occurred in the General Hospital at Calcutta. His personality had won for himself a wide circle of friends both in India and at home. Before his recent appointment he filled the important post of civil surgeon at Lahore, where his loss will also be deeply mourned.

### THE HEALTH OF THE ARMY.

At a meeting of the National Service League held at Hale, near Farnham, on Jan. 18th, Sir Thomas Gallwey, K.C.M.G., A.M.S., principal medical officer of the Aldershot Command, said that he had recently drawn up a report on the health of the army for 1910. The making of that report had forcibly impressed upon him the fact that the present excellent health, both physical and mental, was due to the physical training and discipline which had been introduced since the South African war. The British soldier of the present day was more intelligent and active and better in every way than in the old days. Last year the men admitted to hospital were only half in number in comparison with those admitted in the previous five years. The waste of the army also showed a striking decrease. This last year when he made up the returns he found a reduction of nearly two-thirds, the actual rate being 9 per 1000.

### THE ROYAL NAVY LIST.

Among the books of reference which have earned for themselves the title of indispensable a place must be found for the Royal Navy List, published by Messrs. Witherby and Co., the 113th quarterly volume of which has just been issued. The information given in this book concerning the Royal Navy and its *personnel*, both active and retired, and the ships of the fleet, is arranged in a manner at once concise and easy for immediate reference, while the current history of the Royal Navy, a summary of the commissions of ships, and a naval bibliography considerably enhance the value of the List. An addendum corrects the list of officers and their services up to the middle of January. The war and meritorious service section deals with the careers of over 14,500 officers, the information for the most part being contributed by the officers themselves. The publishers are to be congratulated upon the accuracy and arrangement of the book.

### ANNUAL REPORT OF THE SURGEON-GENERAL OF U.S. NAVY.

The annual reports of the Surgeons-General of the three Government services of the United States—the Army, the Navy, and the Marine Hospital Service—always teem with varied and interesting information, of value, partly substantive, partly for comparison, far beyond the confines of the Government to which they are rendered. The annual report of the Surgeon-General of the U.S. Navy for the fiscal year 1910 well repays perusal. The improvement that is taking place all the world over in the care bestowed on those who risk their lives and limbs in the service of their country, as well as in the attention devoted to keeping them in the most effective condition for the purpose for which they exist, is well mirrored therein. We note first a generally diminished damage ratio, as compared with that of the preceding year and of the average of the preceding ten years. The death-rate of 5 per 1000 is lower than has ever been previously recorded. Deaths from drowning appear to be too numerous, and call forth a suggestion that after enlistment, warrant, or commission each man shall be required to demonstrate his ability to swim a substantial distance and to keep his head above water for 15 minutes in the presence of a light breeze. The necessity for "study appointments" to naval hospitals and in civil communities is insisted on, and the encouragement of specialism along certain lines is justified. The establishment of assistant surgeons in the U.S. navy is still undermanned, this fact being attributed, in considerable part at least, to the pay of that rank being below that of officers of equal rank in other services. The difficulty that besets the amateurish system of keeping down the enrolled strength by relying on the power to fill up the establishment with civil practitioners in times of emergency—a practice with respect to Government medical services which a false economy renders tempting to politicians in countries other than the United States—is well illustrated by Surgeon-General Stokes, when he says that it seems to require a considerable number of years for officers to appreciate the fact that a medical officer's rightful duties are manifold, and that administrative, executive, and recruiting activities are quite as much functions of the medical corps as are those of the sick-room and the clinical laboratory. Much attention, apparently, is paid in the U.S. navy to venereal prophylaxis, and the dental work done is also considerable—matters the importance of which to an efficient *personnel* can hardly be denied. Stress is laid on the value of the services that can be rendered by the naval medical corps in times of national emergency other than warfare, and on the aid capable of being given by them to the elucidation of many problems in tropical medicine. Of the prominent hygienic problems of the service importance is attached to the increase in physical training, and the Surgeon-General recommends the adoption of the Swedish system as at present in use in the British navy. With regard to athletics, the conclusion is advanced, as a result of data obtained by both American and European authorities, that not only is participation in the customary athletic contests unnecessary for the development of the best physique, but that the average man, who is more rationally and evenly developed by conservative and recreative gymnastics, without the undue enlargement of the heart muscle that commonly follows specialism in football and rowing, will live longer and be more resistant to disease and will thereby be enabled to render better service. In view of the high admission rate from typhoid fever in the U.S. navy the experience of English, German, and American statistics is adduced in favour of as much typhoid preventive inoculation as can be

effected, at first without compulsion. The special diseases demanding watchfulness in the navy are divided for purposes of consideration into—(1) affections dependent on probable predisposition; (2) those dependent on environment of recruits; (3) those dependent on ship life; (4) those dependent on exotic exposure; and (5) those dependent on special conditions of service. In Group 1 are named hernia, hæmorrhoids and varicocele, astigmatism, enlarged tonsils, flat-foot, epilepsy, middle-ear disease, tuberculosis, potential insanity, incontinence of urine, and previous appendicitis; in Group 2, contagious diseases; in Group 3, epidemic catarrh, acute bronchitis, influenza, tonsillitis, mumps, diphtheria, cerebro-spinal meningitis, pulmonary tuberculosis, heat exhaustion, and thermic fever; in Group 4, typhoid, malaria, dysentery, and skin diseases, especially scabies; and in Group 5, various forms of mental derangement, appendicitis and peritonitis, acute and chronic nephritis, and various infectious and contagious diseases. Among the recommendations made are the establishment of a naval medical reserve corps, the adoption of a readily washable texture and colour for all service uniforms for officers and men, and the search in recruiting for histories of prior appendicitis, urinary incontinence, and a family history of nervous and mental disease. The services rendered by the improvised naval hospital ships *Relief* and *Solace* have, in the Surgeon-General's opinion, demonstrated their great usefulness in times of peace and their close relationship to preparedness for war. Specially built hospital ships, containing 500 beds each, and having oil burners, turbine engines, a cruising speed of the fastest battle-ship, and a wide steaming radius, are called for. Such ships should be commissioned in time of peace, not only to provide drill in organisation, equipment, provisioning, signals, &c., but, above all, clearly to establish a condition of unblemished neutrality according to the Geneva Convention. The Surgeon-General, when Surgeon Stokes, amply demonstrated in the case of the *Relief* the wisdom of vesting the command of such ships in the medical officer, with an expert navigator as his assistant, instead of subordinating the medical officer to a lay commander.

### THE INDIAN AMBULANCE GAZETTE.

The Indian branch of the St. John Ambulance Association, the excellence of whose work has received the cordial approval of Surgeon-General Lukis, the Director-General of the Indian Medical Service, has now its own official *Gazette*, the first number of which, dated January, 1911, now lies before us. It will be published quarterly, and it is hoped will be the means of facilitating the extension of the St. John Ambulance movement in India by serving as an instrument of communication between the various ambulance centres in that country. The first number, which is of quarto size and consists of 40 pages excellently printed, contains reports of meetings at various centres and much information of general interest with regard to ambulance work in other countries. We wish the venture every success.

### BRITISH RED CROSS NOTES.

Lord Cheylesmore presided on Jan. 20th at a meeting held at the Middlesex Guildhall for the purpose of starting a voluntary aid ambulance scheme in connexion with the Middlesex Territorial Force. A proposal to create 11 districts or sections in Middlesex, with centres at Uxbridge, Staines, Hornsey, Brentford, Finchley, Hampton, Harrow, Ealing, Edmonton, Willesden, and Enfield was adopted, and a general committee of the Middlesex County Section, Territorial Branch, St. John Ambulance Association, was formed.

The first annual meeting of the Essex branch of the British Red Cross Society was held in London at the Liverpool-street Hotel on Jan. 18th, when the Countess of Warwick presided. It was reported that 23 detachments had been formed in the county—namely, 15 for women and 8 for men.

A branch of the British Red Cross Society has been formed at Bristol and 253 members and associates have been enrolled.

### PERSONAL STAFF OF HIS EXCELLENCY THE VICEROY AND GOVERNOR GENERAL.

Major F. O'Kinealy, I.M.S., has been appointed Surgeon (dated Nov. 23rd, 1910).

### THE ROYAL VICTORIAN ORDER.

Captain E. S. Worthington, R.A.M.C., who accompanied H R H. the Duke of Connaught, K.P., in his recent tour to South Africa, has been appointed a Member of the Royal Victorian Order (Fourth Class).

### A STAFF TOUR FOR MEDICAL SERVICES.

Lieutenant-General Sir Horace Smith-Dorrien, K.C.B., D.S O., has issued instructions for the collective training to be carried out by the troops of the Aldershot Command during the coming training season. A staff tour for medical services is to be held in March, and divisional and brigade staff tours between the beginning of April and the middle of June.

# Correspondence.

"Audi alteram partem."

## CONTINUOUS INHALATION IN PULMONARY TUBERCULOSIS.

*To the Editor of* THE LANCET.

SIR,—Dr. Burney Yeo's paper in your issue of Jan. 7th inst., ought to have made an impression on all those who are on the look-out for practical methods of affording relief or effecting cures without criticising too closely the *rationale* of the means employed. It may be doubted whether a few drops of creasote under the nose give off sufficient antiseptic vapour to reach the bacilli carrying on their activity in the depths of the pulmonary tissue, and the too-rigid scientist may feel inclined to discard this simple and efficacious method of treatment. His half-hearted recommendation may therefore fail to overcome the fastidious patient's objections to the "nasty stuff." This would be most regrettable, as the method, whether it be the main factor or merely an adjuvant, has proved itself of the greatest value.

In many of the cases of tuberculosis under my sole care or referred to me by my colleagues I have for some time been prescribing it, and I must admit that at first I was actuated by the "ut aliquid fiat" principle. I found, however, that one patient after another obtained relief dating from the time of the continuous inhalation. To many of us the smell of creasote is unpleasant and to the other inhabitants of the dwelling it is often almost unbearable. I have therefore been endeavouring to find a combination which will be as little unpleasant and as much efficacious as possible. The following (dubbed "gutt. cinnam. co.") will be found to combine these qualifications to a considerable extent:—

℞ Creasoti, ʒii.
Ol. Pin. Sylvest., Spirit. Chloroformi, āā ʒiss.
Menthol, gr. x.
Ol. Cinnam., m.v.

The sponge in the respirator (Dr. Burney Yeo's) is kept moist with this mixture.

To most people this is by no means unpleasant, but a few have an intense dislike to the smell and flavour of cinnamon, and in their case oil of citronella may be substituted. The most conspicuous result is the extraordinary diminution of the cough, and apart from any antiseptic or bactericidal effect I consider this a very important factor in the production of the subjective as well as of the objective improvement observable in the larynx. There is probably nothing more disturbing and injurious to the larynx than frequent or continuous coughing, and nothing more certain to induce repeated "auto-inoculation" than the muscular strain which it involves. The "rest" induced by this simple remedy is therefore beyond all price, whatever its *modus operandi*, and I am sure that those who introduce it whole-heartedly into their practice will receive the thanks of many sufferers. It has none of the objections attaching to those remedies which paralyse the coughing-centre as it only checks the useless and not the useful coughs.

Several of my colleagues prescribe the continuous antiseptic inhalation with great frequency and apparently find i beneficial in tuberculosis of the lungs. I can answer for it,

however, in relation to the larynx and recommend it with the utmost confidence.

I am, Sir, yours faithfully,

Cavendish-square, W., Jan. 21st, 1911. DUNDAS GRANT.

*To the Editor of* THE LANCET.

SIR,—The medical profession is greatly indebted to Dr. Burney Yeo and other early pioneers like the late Dr. Sinclair Coghill of Ventnor for their persistent advocacy of continuous inhalation in pulmonary tuberculosis. It was about 20 years ago, while a student at King's College Hospital, when Dr. Yeo was a physician there, that my attention was called in one of his clinical lectures to his antiseptic vapour treatment in pulmonary consumption. Soon after being qualified I put into practice the inhalation treatment when called upon to treat some bad cases of consumption. Ever since I have been an enthusiastic advocate of this method of treatment in pulmonary tuberculosis. When I began the open-air treatment about 12 years ago the sanatorium presented many opportunities of carrying out the inhalation treatment more systematically and persistently. I made very many trials on the volatility of antiseptic drugs and on the efficiency of inhalers. I found that the success of introducing the inhalant into the small bronchial tubes and air-passages was proportionate to the degree of diffusibility of the antiseptic mixture used. I found also that an inhalant consisting of formaldehyde, menthol, pumiline pine, and chloroform with rectified spirit gave the most satisfactory results. Hence I use most commonly the following formula:—

℞ Formalin (40 per cent.), mxxx. (2½ per cent. strength).
Chloroform, ʒi.
Menthol, gr. xv.
Ol. Pin. Pumil., mxv.
Spt. Vin. Rect. ad ʒi.
Ten drops to be sprinkled every half hour.

N.B.—The formalin solution is made by conveying the formaldehyde into the rectified spirit solution, thus making the preparation more volatile.

After one or two weeks when formalin is more tolerated it can be increased to 5 per cent. Also creasote to the extent of 3 to 5 per cent. may be added to this mixture if desired.

As for an inhaler, I have devised one after the model of Dr. Yeo and Dr. Ruata of Perugia. My formaldehyde inhaler is made somewhat larger than Dr. Yeo's (and a little smaller than Dr. Ruata's), to take in more fully the nose and mouth, is more substantially made so as to bear the wear and tear of continuous use for many hours a day, is nickel-plated within and without to give smoothness and durability, and is curved to fit the chin. The inhaler is manufactured by Messrs. Oppenheimers, London.

In our sanatorium the beneficial effect of the inhalation treatment has been so marked and so uniform that during the last few years it has formed a part of the daily routine of the patients. In fact, my experience is that continuous inhalation, when combined with fresh-air treatment and manual exercise, gives better results than any other method of treatment that has been advocated so far by the medical profession. Consumptive patients are apt to get tired of carrying out the treatment at home after awhile unless they are very enthusiastic. The secret of success depends upon the persistent use of the inhaler for many hours a day with deep breathing, combined with open-air living and daily manual exercise. I warmly endorse Dr. Yeo's experience of inhalation treatment and would strongly advocate its administration both in an open-air sanatorium and outside.

I am, Sir, yours faithfully,

C. MUTHU.

Mendip Hills Sanatorium, Wells, Jan. 9th, 1911.

## TUBERCULOSIS AND STATE INTERVENTION.

*To the Editor of* THE LANCET.

SIR,—In your issue of Jan. 21st, the joint honorary secretaries of the Conference on Tuberculosis, recently held at Edinburgh, charge us with making ambiguous and misleading references, in the preface of the second edition of the "Conquest of Consumption," to what took place at the Conference. They give the actual terms of the resolution to which we referred. It was as follows:—

That the special attention of the Chancellor of the Exchequer, Government, and Parliament be called to the great importance of giving the prevention and treatment of tuberculosis a prominent place in the proposed scheme of invalid insurance.

A conference of experts considers the question of the working man in relation to tuberculosis. It decides to ask the Government to consider the *great importance* of dealing in a *prominent* manner with not only the prevention but the treatment of tuberculosis in a State insurance scheme. When we draw the deduction that the Conference could not have decided to take such a step without meaning that some form of State intervention in regard to tuberculosis is necessary, we are accused of saying what is not the fact. For some reason the joint honorary secretaries contented themselves in their letter with a portion of a sentence from our preface. What we wrote was as follows:—

The representative Conference held in Edinburgh, in connection with the annual meeting of the National Association for the Prevention of Consumption, in July, 1910, although divided as to the form which State intervention should take, was practically unanimous in the opinion that some form of such intervention was necessary, and the proposition was supported by leading administrative officers in some of the largest cities in the Kingdom.

Is this comment either ambiguous or misleading? If so, then the Special Sanitary Commissioner of THE LANCET was also in error in his account (July 9th, 1910, p. 120) of the debate on this question at the Conference. He wrote:—

The Conference was unanimous as to the issue, the only difference being whether the desired legislation should be part of a general scheme or a law dealing only with tuberculosis.

We are, Sir, yours faithfully,

ARTHUR LATHAM.

Portland-place, W., Jan. 24th, 1911. CHAS. H. GARLAND.

## RESEARCH DEFENCE SOCIETY.

*To the Editor of* THE LANCET.

SIR,—As it is just three years since the Research Defence Society was formed (Jan. 27th, 1908), we hope that you will kindly find room for a short account of its work during the past year. The number of members, which was about 2800 a year ago, is now 3770; and the number of associates, which was 130, is now 230. Six new branch societies have been formed, making 19 in all. Since January last the following have consented to be Vice-Presidents of the society: The Bishop of St. Asaph, Miss Balfour, Sir George Beatson, Dr. M. G. Biggs, Sir John Carrington, Lord Hugh Cecil, the Bishop of Chichester, the Earl of Durham, the Bishop of Ely, Sir David Gill, Sir Archibald Hepburn, Lord Kenyon, Professor Leith, the Duke of Norfolk, the Bishop of Nyasaland, Mrs. Henry Sidgwick, the Bishop of Stepney, and Archdeacon Watkins.

Since January last the following pamphlets and leaflets have been published by the society:—(1) "Pasteur, Science, and Medicine"; (2) "The Nation and the Tropics"; (3) "Plague in India, Past and Present"; (4) "The Helpfulness of Physiological Experiments to the General Practitioner"; (5) "Report of Annual General Meeting"; (6) "Diphtheria and Antitoxin"; (7) "Inoculations"; (8) "Experiments during 1909"; (9) "Charges of Cruelty against the Rockefeller Institute"; (10) "Fighting the Invisible"; (11) What the Doctor Says"; (12) "The National Welfare"; (13) "The Brown Dog"; (14) "A Question of Religion"; (15) "The Research Defence Society"; (16) "Sleeping Sickness": (17) "Malta Fever"; (18) "Experiments on Dogs"; (19) "In Memoriam, Louis Pasteur"; (20) "Humanity and Science"; (21) "Friends of Animals."

There has been a very great increase, during the past year, in the quantity of pamphlets and leaflets distributed, and in the number of addresses and popular lectures and lantern lectures given by members of the society in all parts of the country. Many debates also have been attended, in London or elsewhere, by the society's representatives with excellent results. We are constantly finding that the great majority of the audience on these occasions, after hearing both sides, is strongly in favour of the views of our society. A large quantity of our publications has been distributed among public libraries and similar institutes; a large quantity also is sold in the ordinary way of publication. During the past few months the society has been represented by stalls held at the following exhibitions: the Church Congress, the annual meeting of the British Medical Association, the Kennel Club Show, and the Birmingham Dog Show.

The Research Defence Society has nothing to do with the actual making of experiments on animals, nor with the administration of the Act; nor does it desire to see the

abolition of restrictions on experiments on animals in this country. It keeps itself to the work for which it was formed three years ago—that is, to make generally known the facts as to experiments on animals in this country and the regulations under which they are conducted; the immense importance of such experiments to the welfare of mankind; and the great saving of human and animal life and health which is already due to them.

We hope that many of your readers will become members or associates of the society, and will help to extend its educational work.—We remain, Sir, yours faithfully,

CROMER,
President.
SYDNEY HOLLAND,
Chairman of Committee.
F. M. SANDWITH,
Honorary Treasurer.
STEPHEN PAGET,
Honorary Secretary.

21, Ladbroke-square, London, W., Jan. 25th, 1911.

## REBATES ON PETROL TAX FOR MEDICAL MEN.

*To the Editor of* THE LANCET.

SIR,—Everyone who has had extended experience of recovering rebates on petrol duty will sympathise sincerely with the complaint of Dr. J. S. MacDonagh in your issue of Jan. 14th. The difficulty appears to be that his retailer could not produce the certificates which, had it been duty paid spirit he sold, he should have been in possession of, or could easily have procured. In all such cases the retailer himself is liable to refund the amount he has charged for duty, and he in turn will readily obtain the same from the original vendor. Very large stocks of spirit were already in the country when the duty first became operative, and the difficulty experienced in sorting deliveries into duty-paid and unpaid was great. This state of affairs has now ceased to exist and the system is worked by the Excise officers most admirably. Indeed, of late it has been marvellous to see how speedily and satisfactorily claims under such a complicated and absurd tax are dealt with.

In view of the dates mentioned in Dr. R W. C. Pierce's letter, may I remind all your readers that claims *must* now be made before the expiry of six months from the date of purchase?—I am, Sir, yours faithfully,

J. EDWARD DAVIES,
Honorary secretary, the Motor Cab Owner-Drivers Association.

Willow-walk, Highgate-road, N.W., Jan. 18th, 1911.

## THE NOMENCLATURE OF THE SUPRARENAL PRINCIPLE.

*To the Editor of* THE LANCET.

SIR,—As in the issue of THE LANCET for Jan. 7th, p. 73, you allude to the use of the word "adrenine" as a synonym for "adrenalin" and question its accuracy, as it occurs in a note in the "Year Book of Pharmacy," 1910, p. 177, dealing with an abstract appearing in THE LANCET of Oct. 2nd, 1909, of a paper by Mr. J. L. Jona, published in Australia, on "Adrenalin as an Emergency Treatment in Cases of Non-corrosive Poisoning," perhaps you will allow me to endeavour to justify its use on the following grounds.

In his original patent (1901, No. 1467) Jokichi Takamine expressly states that "this is an invention to procure the active principle of suprarenal glands ..... named adrenalin or *adrenin* (the italics are mine) in a pure condition." In view of the number of diverse trade names applied to what is, or should be, a definite chemical substance of an alkaloidal nature, the committee of publication of the "British Pharmaceutical Codex" have adopted Takamine's alternative synonym, with the addition of "e" to denote its basic nature, and have used the word "adrenine" in this sense. As tending to lessen confusion and to increase accuracy I have in the "Year Book of Pharmacy" adhered to this nomenclature. The necessity for the adoption of this common denominator is well illustrated in the case of two abstracts appearing in the current issue of the *Journal de Pharmacie et de Chimie*, 1911, vol. iii., pp. 78, 79. Here the word "suprarenine" is used in the first article by O. Gros, and "adrenaline" in the second by A. Lawen, although the latter paper is complementary to the former, and both authors evidently allude to the same substance. If these papers are abstracted in the "Year Book of Pharmacy" it will certainly be under the title "adrenine."

The inference in your note that the word "adrenalin" is a proprietary word is hardly tenable. It is stated by T. Maben, in a paper on "Adrenalin, the Active Principle of Suprarenal Gland" (*Pharmaceutical Journal*, 1907, vol. lxxviii., pp. 388–390) that "adrenalin is not a registered trade-mark nor a fancy name. It is a truly descriptive word, meaning the active principle of the adrenal structure ..... while the manufacturers ..... claim no proprietary rights over the name." Therefore, the injustice done to a "preparation" by the use of one or other of Takamine's synonyms is not very apparent. The injustice, if any, arises entirely from the loose manner in which trade names and proprietary euphemisms are applied to these newer remedies. This has caused them as a class to fall into disrepute, and has reflected hardly on the few more valuable therapeutic articles among them.

The "belief" expressed in your note that the word adrenine has been submitted to, and rejected by, the General Medical Council is groundless. That body has never considered the question. But had it done so that would have proved very little. It is evident, therefore, that most of the grounds on which your note appears to be based can hardly be considered accurate.

Moreover, it is no function of the "Year Book of Pharmacy" in its abstracts to advertise either "preparations" or persons. These abstracts are intended solely to record scientific facts or practical details of use to pharmacists in their calling, or to those who are interested in the subjects with which they deal.

I am, Sir, yours faithfully,

J. O. BRAITHWAITE,
Editor of the "Year Book of Pharmacy."

Chingford, Jan. 18th, 1911.

## INOPERABLE CANCER.

*To the Editor of* THE LANCET.

SIR,—I was much interested to see from a letter in THE LANCET of Jan. 14th from Dr. Alexander Haig, asking that inoperable cases of cancer might be sent to him, that he has met with the same difficulty as others in obtaining such cases for the purpose of testing a theory or new form of treatment. As I have been on the outlook for such cases for a number of years I can heartily sympathise with Dr. Haig, and at the same time can, I think, point out how the difficulty arises. It is in this way—we have been brought up to believe that a case of cancer beyond the operative stage must of necessity die, with the very rarest exceptions, and where such a case is met with the doctor naturally says incurable, and that is practically the end of it. One has this feeling one's self, for when a case is, or at least appears to be, cured, one begins to have doubts of the diagnosis and to wonder if, after all, the patient ever had malignant disease.

Another reason is that it has become the fashion to say that we must know the cause before we can expect to find a cure, though this is against all medical history. We require to persuade medical men to send at least their poor inoperable cases to anyone who is working on new and what he believes to be hopeful lines, and not stick to the old groove of "try nothing." I am, Sir, yours faithfully,

Upper Berkeley-street, W., Jan. 19th, 1911. SKENE KEITH.

## THE INFLUENCE OF TOBACCO ON DIGESTION.

*To the Editor of* THE LANCET.

SIR,—THE LANCET in an annotation in its issue of Dec. 31st, 1910, gave its readers interesting information anent the dangers of tobacco smoking to sufferers from hyperacidosis; and I agree with much that you stated. I think, however, that there are one or two other contributory causes of this syndrome than those mentioned, which, with your permission, I shall here point out. My experience as a pipe-smoker, which extends over half a century, during much of which time I have also had occasional attacks of hyperacidosis, confirms my belief that these contributory causes

are mainly three: first, constipation; secondly, nervous excitement, such as may be caused by reading after a full meal an interesting novel, or maybe a somewhat controversial article in THE LANCET; and thirdly, as a result and meanwhile, the rapid suction of the pipe's mouth-piece. This quick puffing of the smouldering pipe is in my opinion the real cause of the trouble. It is well known that any action which promotes the flow of saliva will probably stimulate the peptic glands also. In my own case the rapid suction of an empty pipe, if other symptoms are favourable, will bring about these untoward results as readily as will one too tightly packed with alien tobacco from a friend's pouch (I am partly Scot by descent). Briefly, I may sum up my experience of this slow (very slow) poison in the following doggerel:—

Learn to smoke slowly. No pipes that draw
Will injure your over-acid maw;
'Tis violent suction starts the bane
Bequeathed to smokers as gastric pain!

I am, Sir, yours faithfully,

Hove, Jan. 14th, 1911. W. A. H.

# THE HOUSING PROBLEM IN SOUTH WALES.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(*Continued from p. 194.*)

### *A Bad Slum on a Choice Site.*

OF the various slums for which Merthyr Tydfil has acquired an unenviable reputation perhaps Company-row is the most notorious. This may be due to the fact that it was specially denounced in Dr. J. Spencer Low's report to the Local Government Board or because it is on the main road between Merthyr and Dowlais and is easily found. The sanitary authorities, however, seemed inclined to challenge the claim made that Company-row was the worst place, so that its inhabitants are even denied the melancholy privilege of being the most to be pitied. In fairness I must say that on visiting the place it soon became evident that the tenants remaining in Company-row were enjoying a far more liberal share of open space and invigorating mountain air than generally befall the lot of the submerged in large industrial communities. Facing this row of one-storey cottages is a wide open space that only needs to be paved and kept tidy. The soil has been converted into black mud consisting of a mixture of soot and coal dust—not unhealthy substances in themselves as part of the soil, but they help to make the people and surroundings look dirty and grimy. A few flagstones were placed in front of the cottages and here also were gullies leading to drains for the slop water. These slop drains in front of the cottages were ventilated, and so were the closet drains, which are all at the back of the cottages. When I entered one of the cottages it seemed very miserable. There was no wooden or even tile flooring, but flagstones such as are used for a street causeway. This must be very cold in winter. Fortunately, coals are cheap, and in all the houses, however poor, I noticed there was a bright, glowing fire. These cottages are dirty, overcrowded, and miserable; but with a glorious look-out at the back. There were no houses blocking out light and air. A deep descent to a mountain torrent rendered building operations difficult. Thus a wide space is kept open, and the waters, as they rush along below, help to stir and cool the air, so that for hot, sultry, summer days this spot might be made the site of pleasant residences. It is true that the steep hill on the other side of the torrent could be sneeringly described as a sham mountain, for it was not made by nature, but is one of the numerous "tip" hills that arise as the result of tipping the refuse from the mines and foundries. There is, however, nothing unwholesome about these modern and manufactured mountains, though it must be confessed that the grass which strives to grow upon them looks very yellow and unhealthy.

### *German Slum Children: a Contrast.*

With this splendid expanse of valley, hills, and uninhabited country at the back, and a wide open space in front, with both slop and soil drains situated outside the cottage walls, and no soil pipes under the cottages, it has rarely been my lot to visit slum property so fortunately situated. When I recalled the sight of the children in, for instance, the cholera districts of Hamburg, living in courts so narrow that it is possible to shake hands with the person looking out of the window opposite, and where the houses were at least five storeys high, I could not but think that these Welsh children were to be envied their air-supply. But when I examined the children themselves and saw that evidently there was no housewife to look after them, that there was no one to wash them, or brush them, or mend their clothes, then it was the children of the cholera slums of Hamburg that were to be envied.[1] Indeed, what I said of the slum-dwellers in Hamburg is the one great lesson that has to be conveyed to the British poor, not only in South Wales, but in many other parts of the country. In visiting three years ago one of the worst cholera slums of Hamburg which were still intact I said, speaking of its poor inhabitants:—

> On them at least the lessons of the great cholera epidemic have not been lost. They have learnt that cleanliness and plenty of air were the best of preventives. My photographs testify by the numbers of windows that are open how these poor people are striving to make the most of what little air is able to penetrate the narrow courts in which they are compelled to dwell. As for the cleanliness, the best evidence was the appearance of the children. Some looked poor and pinched and anæmic, but out of some hundred or more children whom we saw and carefully observed in these courts not one was untidy or dirty. Their clothes might be made of poor materials, they might be patched or darned, but not in one instance were they torn or disorderly. As for the little girls, it was simply beautiful to note how carefully their hair had been combed, brushed, and dressed, and clustered round their clean and well-washed faces. Yet these were the slum children of Hamburg, bred and born in those very slums, unaltered and even still more overcrowded, where the inhabitants had been decimated by the terrible cholera epidemic of 1892. M. Rey, like myself, was deeply impressed, and he kept saying, "See, see, what a brave fight they are making for existence even here, where everything is against them." If in spite of the continued existence of such slums and of the neglect of the interest of the poor, the death-rate of Hamburg is falling and there has not been another great epidemic, the honour is due to the Hamburg housewife. By keeping her children clean she has proved herself the most practical of all the sanitary reformers.

At Merthyr the verdict must be the exact opposite. If the death-rate is falling, this is due to administrative measures rather than to any special care or concern displayed by the poorer class of housewives. Instead of making a brave fight for existence the poor here fall into a state of general apathy; they no longer care how dirty and ill-kept their homes become. Cottages that might be quite pleasant habitations become dilapidated, dirty, and overcrowded. The inhabitants rarely wash and never mend their clothes. They have no pride, the women are slatterns, there seems no discipline at home, and the pressure exercised by the medical examination of the children at school is not yet sufficient to keep them clean and tidy. It would appear as if no one cared, neither the parents, the children, nor the community at large. No one seems ashamed. Amidst picturesque scenery and hills, where there is the purest mountain air and all that is required to make life beautiful and exceptionally healthy, a hideous town has been built and a large mixed population allowed to gather together without any thought of the degradation likely to ensue, for at first there were no regulations, no restraints, and no educational influences of a practical nature. While the main streets were built without any plan leading to architectural developments and harmonious combinations, the slum dwellings erected immediately behind them were constructed in defiance of laws of health or decency. Thus a beautiful country has been rendered hideous and unhealthy. The very hills that should contribute most effectively to the beauty of the district and to the health of its inhabitants have been disfigured by squalid people, living in ugly and unwholesome dwellings. Everyone knows that by building on the hillsides rows of houses one above the other the direct rays of the sun can reach and purify each house. In the same way the passing winds help to destroy and carry off all impurities. The difficulty of building healthy houses in the great centres of population is due to the impossibility of securing sufficient open space around them. But here, on these Welsh mountains, the houses can be built one above the other, and thus cannot cast each other in the shade. Will it be believed that, instead of profiting to the full from this inestimable advantage and securing for every house all the air possible, both back and front, holes have been dug into the mountain side and semi-cave dwellings artificially created?

### *The "Over and Under" Houses.*

These "over and under" houses constitute the special grievance of South Wales. Company-row is an example of

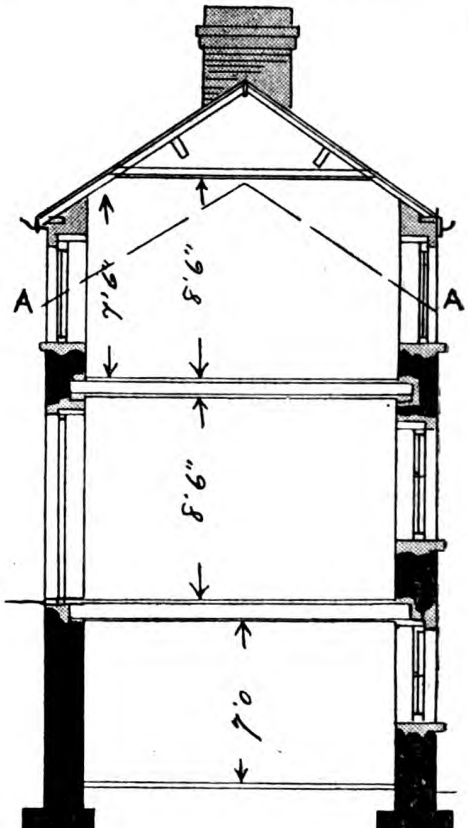
[1] See THE LANCET, Dec. 14th, 1907, p. 1728.

this abomination. The house that is "over" is fortunate, because it rests on another house, and therefore on a dry foundation, and it has open space both back and front. But the "under" house has no back space at all. The back is close upon the mountain side. The wall of the back room is built up against the bare earth, and, of course, the damp comes through. In some cases these "under" houses are of two storeys. Here and there an attempt has been made to separate the backs from the mountain side by cutting a trench down and making a sort of area a few feet wide and two storeys deep. This certainly does mitigate the dampness, but it provides very little air and no light whatsoever. Just below and at the back of Company-row is an old road on which the "under" dwellings give. It is an historical road, for here it was that Trevethick, the precursor of Stephenson, drove his traction engine. This primitive locomotive was provided with a brick-built chimney or funnel. Trevethick had a wager that he would draw a load of ore along at the rate of eight miles an hour. This he did easily, but the shaking was too much for the chimney and it fell clattering on the road which passes under the cottages of Company-row. The spot should be the pride of the town, and here some of the worst slums have been allowed to come into existence. But these are the sins of days gone by. Nothing of the sort could be done now. There are severe by-laws governing the construction of new dwellings. The difficulty is to efface the ugly traces left of the ignorance and indifference of past generations. This work of obliteration and reconstruction never seems to proceed fast enough. In any case, Company-row has been dealt with in a most summary and radical fashion. All the "under" houses are closed. Strong planks are nailed over the doors and windows. There is no admission possible, not a soul is living in them. Indeed, it is only necessary to look down the long list annually published of houses condemned to see that it is these "over and under" dwellings which are the most energetically attacked. Yet there are still some remaining if only to bear witness to the abominations that prevailed in the past. This is notably the case at Merthyr Vale where some of the under houses are two storeys high. Viewed from below, these houses appear four storeys high. But while the two lower floors are fronts of houses, the two upper floors are backs of houses which have their frontages and entrances on a street behind and on a higher level. In many cases where such dwellings have not been altogether abolished, the lower portions have been condemned, at least as sleeping apartments, a staircase to the upper portion built, and the two separate houses thus connected. The accompanying drawing of a section illustrates such a transformation. The A line indicates where the roof used to be; but now the walls have been raised and new and better roofs put on, so that, instead of sleeping in a low garret, the inhabitants have a fairly lofty bedroom with a ceiling and thorough ventilation. The thick, black vertical line to the left shows the level of the earth on the higher road. To the right at the lower level is the lower road, where are one-roomed tenements only seven feet high built with their backs to the earth of the mountain side. These as separate tenements and dwellings have been abolished altogether and converted into sculleries, washhouses, cellars, or lumber rooms for the house above.

*A By-law Enforcing Cleanliness.*

There were also a large number of back-to-back houses, and these have been dealt with in many cases by cutting through the partition walls and throwing two houses into one. By thus making two houses into one not only can a through draught be established, but in several cases the number of inhabitants became sufficient to enable the authorities to register the dwelling as a house let in lodgings. It then comes under a very useful and stringent by-law enacted on Oct. 21st, 1907. This must not be confused with the old Common Lodging Houses Act of 1851. The new by-law applies to private lodgings in private houses where the rent is under 5*s.* a week for unfurnished and under 7*s.* 6*d.* a week for furnished lodgings. Then it stipulates that each adult shall have 400 cubic feet of space and each child under 12 years 200 cubic feet. The sexes are to be separated. The sanitary inspectors have the right of entry both day and night. There must be one closet for every 12 inhabitants. The whole of the premises must be kept thoroughly clean. All the floors must be swept every day and scrubbed every week. All slops and refuse must be removed from within the house every day. All the windows must be fully opened for at least one hour every morning and every afternoon. Immediate notice of any illness has to be given to the authorities. It will be admitted that to bring some of the worst property and the most careless and dirty of the inhabitants of Merthyr under such a law as this is no slight achievement.

In spite of all these efforts much remains to be done, and there are yet many deplorable places to be seen. Some are closed up like Crystal Palace-court and other and smaller courts, all neighbours of Company-row. Others are condemned but not yet vacated. Some of these houses have been allowed to fall into a very dilapidated condition. Of 300 to 350 little cottage houses at Old Dowlais, about 135 are inhabited by two or more families, and yet these houses have rarely more than four rooms. There



An "under and over" house transformed. The thick black line is the portion of the wall touching the mountain side against which the "under" house is built. This is a one room tenement giving on to a road to the right. The "over" house gives on a road to the left and at a higher level. The line A A indicates the roof of the former garret bedroom.

is here one celebrated slum named, perhaps out of a spirit of derision, Garden-row. It consists of a row of little yellow-coloured cottages with no backs, and in front the upper windows are about 23 by 19 inches. In many cases there is no ceiling upstairs. The beds are under the bare rickety tile roof. The rafters are rotten, the rain passes through easily, and the whole structure threatens to fall in. The chimney stacks are also a menace; they have completely lost their original shape as so many bricks have been detached and blown off. One of the upper rooms which I visited measured 3 feet 6 inches in height by the eaves and 7 feet at the apex. Naturally, there was no ceiling. The windows for the bed-rooms thus situated were 18 inches square, including the framework; the actual opening for the passage of air was only 16 by 14 inches. There is also in this district a terrible little

court off Wild-street which abuts against a high building that very effectually helps to keep out the air. Here are old back-to-back houses where doors have been cut through the partition walls, but as the doors are generally, and carefully, closed the houses become in effect back-to-back houses once more. Some of these, though back-to-back houses, have in front of them only very narrow and dark courts. Naturally, this greatly accentuates the evil. Finally, such doors and windows as exist are very small. In Garden-row, in Tissington-court, and other thoroughfares and courts of this neighbourhood several houses have been closed altogether, but many more remain which do not deserve better treatment.

*(To be continued.)*

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

### *The Health of the City.*

IN the quarterly report to the health committee the medical officer of health, Dr. J. Robertson, gives a brief summary of the statistics for last year. The figures are subject to revision, but accepting them as approximately accurate I find that the death-rate for 1910 was the lowest on record, 13·7, as compared with 15·5 in 1909. The zymotic rate is also the lowest recorded, 1·1, 1907 coming next with 1·8. The infant mortality, 130 per 1000 births, was again a satisfactory record and an improvement upon 1909 with 135. Phthisis is steadily upon the decline, the death-rate from this disease being 1·15 last year. The cases of typhoid fever notified were also fewer than ever before—73. The birth-rate last year was 26·2, smaller than in any previous year.

### *Midland Counties Home for Incurables.*

The annual report of the committee of the above home stated that the receipts for 1910 were £7513, compared with £7663 in 1909. Subscriptions were £46 less, donations £103 less, and patients' payments had fallen from £3019 to £2949. This last decrease was due to the fact that the committee had felt able during the year to create four additional free beds, and to reduce the charges for the partially paying patients when temporarily absent from the home. Every additional privilege of this nature made a fresh demand upon the income derived from endowments, subscriptions, and donations, and it was therefore regrettable that these should have diminished. To help in obtaining fresh sources of income, the committee was trying to obtain the services of honorary local correspondents in the various districts served by the home. During the year £3000 had been added to the invested funds.

### *Gas Lighting in Relation to Public Health and Smoke Abatement.*

At a meeting of the Midland Association of Local Government Officers, Mr. R. J. Rogers, lighting superintendent of the Birmingham Gas Department, read a paper on the Use of Gas in Relation to Public Health, with special reference to Smoke Abatement. Mr. Rogers said that with regard to the ventilation of a room, not only was the use of gas economical, but it was hygienically superior to any other system of artificial illumination. The advocates of electric light contended that electric light was superior to gas because it did not consume or vitiate the air, that it created no heat, and did not damage decorations. He quoted opinions of authorities in support of his argument that the use of gas-lighting of high candle-power had been proved to be conducive to a healthy atmosphere and to the well-being of the public who frequented the rooms in which it was used. Theatres and music-halls were generally provided with a large central sun-burner fitted with flat-flame gas-burners. The primary use of this sun-burner was for ventilation, but with the more general use of electric lighting in theatres these sun-burners had been more or less neglected, and were not sufficiently used considering their very efficient action in drawing the vitiated air out of the theatre. With regard to smoke abatement, Mr. Rogers said much had been achieved, but it was necessary for the interest of the citizens generally to be aroused. The Birmingham town-hall and council house showed unmistakeable signs of the disintegration caused by smoke. The gas-engine had done much to lessen the amount of factory smoke. London, Glasgow, Sheffield, Leeds, Manchester, and other industrial centres had their own smoke abatement societies, but in Birmingham there was no such society, and he urged the formation of one.

Jan. 24th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### *Liverpool School of Tropical Medicine: Expedition against Sleeping Sickness.*

ON Jan. 19th at the Adelphi Hotel, Mr. W. H. Lever (the chairman of the school) entertained at dinner a large gathering of gentlemen interested in the work of the School of Tropical Medicine, or connected by business ties with those tropical regions in which the good results of that work have already been seen, in order to bid *bon voyage* to Professor J. L. Todd, Dr. Wolbach, and Mr. Ernest D. Todd, who proceeded to Gambia and Senegal on Jan. 21st to investigate sleeping sickness. The chairman was supported by Professor Todd, Dr. Wolbach, Mr. Ernest Todd, Sir Owen Phillips, K.C.M.G. (Vice-President of the school), Sir William Bowring, Bart., Sir Edward Russell, Sir Alfred Haslam, Professor Sir Rubert W. Boyce (dean of the school), Professor Ronald Ross, C.B., Professor H. E. Annett, and others. The loyal toasts having been duly honoured, the chairman proposed "Our Founder of Revered Memory," and asked the company to turn down their glasses in remembrance of Sir Alfred Jones. The toast was acknowledged in solemn silence. The chairman then submitted the toast of "The Twenty-seventh Expedition of the Liverpool School of Tropical Medicine," and said that they had every reason to feel proud of what the Liverpool School had done in regard to tropical disease. The present King of the Belgians took a great interest in the movement and recognised its paramount importance. The school was greatly encouraged and stimulated by the progress it had made, despite the fact that the Government had rather turned its back on them. It would interest them to know that the Liverpool School had raised nearly £100,000 for the investigation of tropical disease. But the Government had been lax in dealing with those diseases. It was necessary that something should be done if we were to retain our tropical possessions. Many of these at present were the happy hunting ground of the mosquito and other pests of tropical life. They advocated such measures being taken as would not only prevent epidemics breaking out, but make the tropics the healthiest part of the world. Well, he believed that they were gradually doing it. The methods by which the Government approached this subject did not commend itself to any who gave scientific attention to this matter. The Liverpool School was advocating measures to prevent disease and to make the tropics habitable for the white man. It was a greater thing for the governor of a tropical state to look after the cleanliness of the town in which he was stationed than to lead a punitive expedition to butcher niggers in the bush. Professor Todd, in reply, said that the study of tropical medicine was not only important to Great Britain but to the world. They should endeavour through the press to stimulate public opinion and keep alive interest in the great work that was being done. Dr. Wolbach also replied, and said that he desired to pay a tribute from Harvard University as to the work the school was doing in the way of tropical research. His university recognised that there was no better school than that of Liverpool. The aim of the present expedition was either to verify or disprove the at present accepted theory with regard to sleeping sickness. Sir Edward Russell proposed the toast of "Commerce and Medical Science," which was replied to by Sir Owen Phillips, Sir Rubert Boyce, and Professor Ronald Ross.

### *The Medical Society of Liverpool.*

At the annual meeting of the Liverpool Medical Institution held on Jan. 19th Dr. T. R. Bradshaw, the President, moved on behalf of the council, the following resolution:—

That the name "The Liverpool Medical Institution" be changed to "The Medical Society of Liverpool."

The necessary two-thirds majority of those present and voting having been secured, the motion was carried. Professor C. S. Sherrington, F.R.S., was elected a vice-president of the society.

*New Accident Hospital at Garston.*

The finance committee of the city council has had under consideration the advisability of giving financial aid towards the erection of a hospital at Garston, the most southern district of the municipality. A special subcommittee has made a report to the effect that an offer be made, without admitting liability, to the committee of the proposed accident and emergency hospital at Garston and district to contribute £5000 towards the erection of this hospital. The original proposal of the finance committee was to grant a sum of £4000, but by the casting vote of the chairman the increased amount of £5000 was carried.

Jan. 24th.

## WALES.

(FROM OUR OWN CORRESPONDENT.)

*Cardiff Water-supply.*

THE heavy rainfall of last year has increased the amount of water in the Cardiff reservoirs very considerably. The average rainfall for the past 26 years on the gathering grounds which serve the Brecknockshire reservoirs was 79 inches, and in 1910 it was 92 inches. The amount of water now in store in the corporation reservoirs is equal to about five months consumption, based upon an average per head daily of 27 gallons. In spite of this satisfactory condition and in view of the anticipated growth of the borough the corporation has begun the construction of the third and last reservoir in Brecknockshire. It is expected that the completion of the undertaking will not be attained until about six years hence, when there will be a total storage capacity of 2265 million gallons.

*Scarcity of Houses in Swansea.*

It was anticipated that the exhibition of workmen's dwellings, erected on land owned by the Swansea corporation, which was held last year, would have led to the erection by private enterprise of an increasing number of working-class dwellings. This anticipation has not been altogether realised, though the corporation has decided to add to the number of cottages it already possesses by erecting several hundred more. The scarcity of such dwellings is indicated by the statement of the corporation rent-collector that for one empty house he had received 98 applications and that 560 persons had applied for some of the new houses.

*Swansea Hospital.*

The board of management of the Swansea Hospital has decided to appoint a fourth out-patient medical officer and to create a new appointment of assistant ophthalmic surgeon. To the latter position Mr. H. E. Quick, a former house surgeon of the hospital, has been elected. A proposal has been made that the hospital management and the corporation should coöperate in the establishment of a pathological and bacteriological department, and that in association with it the vaccine-therapy department of the hospital should be carried on under the supervision of an honorary medical officer.

Jan. 24th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*Edinburgh School of Medicine for Women.*

AT the Edinburgh School of Medicine for Women, in which the lecturers are recognised as giving qualifying courses for graduation in the University of Edinburgh, 74 students have been enrolled during the winter. Of these, 64 are working with a view to University graduation and 9 for the triple qualification.

*Annual Report of Chalmers' Hospital, Edinburgh.*

At the anniversary meeting of the Faculty of Advocates, held on Jan. 18th, the directors of the Chalmers' Hospital reported that the number of patients treated during the year was 602 in all—373 of those having been treated in the free wards and 229 in the private wards, paying board. Of the 602 cases, 345 were surgical and 257 medical. Operations numbered 380. The out-patients numbered 3214, of whom 2835 were surgical and 379 medical. Operations under general anæsthesia in the out-patient department numbered 188 and dressings 17,236. The ordinary income for the year amounted to £4073 7*s.* 9*d.* and the ordinary expenditure to £3564 7*s.* 9*d.*, leaving a surplus of £508 10*s.* 3*d.* This surplus, increased by the accumulated surpluses of previous years, amounts to £1473 5*s.* 3*d.* The directors are considering alterations and extensions to the accommodation of the hospital, but could not yet submit any definite scheme to the Faculty. A lady, who wished to remain anonymous, has offered to defray the cost of erecting a covered verandah outside the female private ward. The offer has been accepted, and the verandah, which cost £200, has proved a great boon to convalescent patients.

*School for Cripple and Invalid Children in Edinburgh.*

The Edinburgh school board has recently purchased three small villas in Duncan-street and South Gray-street which are to be used as schools for mentally deficient and cripple and invalid children. One of the houses has already been altered and is in use as a school for mentally deficient children, and warrant was granted this week by the Dean of Guild Court to make alterations in the other two. Accommodation for cripple children will be on the ground floor, and will consist of three class-rooms, each holding classes of 20, a large dining-room, and a new entrance hall. On the upper storey there will be class-room accommodation for invalid children and a large hall. On the south side of the building there will be large verandahs where classes will be taught in fine weather, and on to which the class-rooms will open by means of folding doors. Hot-water pipes will be used for supplementary heating, but the class-rooms will be provided with open fire-places.

*Appointments in the University of Edinburgh.*

Dr. A. H. F. Barbour has been reappointed Lecturer on Gynæcology, and Mr. J. W. Dowden has been appointed an Examiner in Surgery and Practical Surgery.

*Epidemic of Diphtheria in Arbroath.*

An epidemic of diphtheria has broken out in Arbroath and district. Since the middle of December 49 cases have been admitted to the hospital.

*Medical Inspection of School Children in Aberdeen.*

In connexion with the question of treating and cleaning verminous school children the public health committee of the Aberdeen town council has now presented its report. It will be remembered that the communications from the school board requesting the coöperation and assistance of the sanitary authority in this matter were remitted by the council to the public health committee. The committee is of opinion that the town council should coöperate with the board in any practicable measures suggested for the purpose. It recognises that the presence of body vermin in a family is nearly always associated with a lack of personal cleanliness, and indeed with cases that would justify active interference by the public health department. The committee is not sanguine that permanent results will follow from any system of dealing with the verminous condition until a higher standard of cleanliness is reached in the affected households, and it is therefore disposed to believe that the most valuable effect from any measures that might be taken would be the stimulation of a stronger sense of cleanliness. It believes that, except in the case of parents who are altogether lost to a sense of shame in having their children sent home from school as filthy and verminous, the work of the medical inspectors of the board will probably in course of time appreciably raise the standard of family cleanliness, and thereby lead to a corresponding decrease in vermin. It is satisfied that the public health department has so far done all that can be done in present circumstances, and has indeed attempted more than in almost any other town regarding which it has information. Without venturing on an opinion as to what degree of permanent benefit may result from the application of radical measures in a large proportion of the cases of verminous households, the subcommittee recommends that as soon and as far as may be practicable a combined effort by the school board and the town council should be made to bring such measures into operation and to give them a fair trial. The annual cost of carrying out the proposal would amount to about £655, which would be borne by the town council and school board equally. If special premises have to be erected for dealing with verminous persons the total annual cost would be increased to not less

than £800. It would be desirable, in order to estimate the effective value of the whole work and to enable both the board and the council to ascertain whether they would be justified in undertaking it on the radical and somewhat expensive plan suggested, that all the children should be inspected for body vermin, say, every two or three months, and that, if desired, facilities should be given to the public health department for being represented at the inspections. The subcommittee has not in its estimate of expenses made any allowance for the cleaning of houses and the washing of clothing and bedding, and if such were undertaken the expenditure would be increased by £200 or £300 annually. With the view of carrying out the suggested arrangement an agreement between the council and the school board has been prepared.

*Medical Inspection of Schools in Caithness and Sutherland.*

A meeting of the Caithness Secondary Education Committee was held at Wick on Jan. 21st, when an important letter was submitted from the Education Department as to the appointing of a school medical inspector for Caithness. At present Dr. G. Dick of Wick is joint medical officer of Caithness and Sutherland, and the Department recommended that the two counties should be separated for public health purposes and an officer appointed to look after public health and school medical inspection in each county. After some discussion, it was agreed to offer the appointment of school medical inspector for Caithness to Dr. Dick, on condition that he gives up the medical officership of Sutherlandshire, the salary to be not less than his present emoluments. The county council subsequently fell in with the arrangement, and it was remitted to a committee with powers to approach Dr. Dick.

*Complimentary Dinner to Sir David C. McVail.*

Last week Sir David McVail was entertained at dinner by a large gathering of lay and professional friends in recognition of the honour of knighthood recently conferred upon him. Dr. D. N. Knox, President of the Royal Faculty of Physicians and Surgeons, Glasgow, occupied the chair and proposed the toast of the evening. After a tribute to his work as professor of physiology in Anderson's College, Dr. Knox said that their guest there joined Dr. Ebenezer Duncan, Dr. Reid, and himself in forming the Western Medical School in Glasgow. There he taught systematic medicine until he was transferred to the Royal Infirmary and became the professor of clinical medicine in St. Mungo's College. All this time Dr. McVail was thinking over the great question of medical reform, and the first intimation he gave on the subject was an introductory lecture he delivered in the Western Medical School on the teaching of medicine in Glasgow. It created considerable talk at the time, and immediately thereafter, in the early "eighties," the great question of medical reform came before the Scottish Universities. When the Bill of 1889 became a statute there was no doubt that it was to the skill, determination, and generalship of Dr. McVail that any benefit they had received from the Act was due. The affiliation clause was directly due to his efforts. The chairman also referred to their guest's services as a member of the University Court, and to the honour conferred on him 15 years ago by his appointment as Crown representative for Scotland on the General Medical Council. Sir David McVail, in acknowledging the toast, gave many interesting reminiscences of olden times in the Royal Infirmary, dealing more especially with the work of Lord Lister and Sir William Gairdner. At a later period of the evening Dr. John Patrick, on behalf of his old house physicians and students, presented Sir David McVail with a silver salver, candlestick, and flower vases, in recognition of their high regard and to mark the honour conferred upon him.

*Scottish Poor-law Medical Officers' Association.*

The report of the committee of this association for 1910 says that during the past year much correspondence has taken place with outgoing medical officers of over 25 parishes, all but two of whom courteously supplied on request detailed information regarding the appointments. The committee has obtained authoritative information, where necessary, and given advice in the matter of several problems submitted; for instance, appointments are absolutely at the discretion of the parish council, so that a non-resident appointment made thereby holds good even though there be a medical man resident in the parish. The Secretary for Scotland, Mr. J. Cathcart Wason, M.P., has replied to a query that he sees no chance of the Parochial Medical Officers (Scotland) Bill being considered in Parliament in view of the report of the Royal Commission on Poor-law, until the Government shall attempt legislation on the lines of the report. When that takes place Mr. Wason will have an opportunity to get the grievances of the Scottish Poor-law medical officers remedied. The secretary announces that he will always welcome communications from the members, which will, on request, be held as private and confidential, unless from the members of the committee. The annual meeting for 1911 takes place at the St. Enoch Station Hotel, Glasgow, this week, when the report will be submitted and new officers will be elected. Owing to deaths and resignations the numbers of the society are diminished, and new members are urgently asked for. The subscription is 5*s.* per annum. The financial report for 1910 shows assets £185 14*s.* 4*d.*, expenses £23 6*s.* 11*d.*, balance £162 7*s.* 5*d.* The present secretary is Mr. W. L. Muir, 1, Seton-terrace, Glasgow.

Jan. 24th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Insanitary Primary Schools.*

ON many occasions in the past few years attention has been drawn to the insanitary conditions of the Irish primary schools and to the neglect of hygienic considerations shown in the conduct of the schools. The Dublin Sanitary Association has recently had the subject under investigation and has published an important report thereon. The report quotes from Mr. Strong, an inspector of schools, who, in speaking of the schools in his district, says: "There are many of these unsuitable houses in the city of Dublin—one in the crypt of a church—badly lighted, heated, and ventilated; and another in an old dwelling-house, whose former drawing-room is the school-room." It is, of course, the fact that the Board of National Education has no direct control over school administration, but it has the very important power of withholding the grant in aid unless the school is "conducted in accordance with the regulations of the Commissioners." It is therefore well within the power of the Board to refuse the grant unless the schools are conducted in accordance with the demands of hygiene, but it cannot be discovered that they have generally exercised pressure in such a direction. Moreover, since 1892 attendance at school has been compulsory in cities and corporate towns as well as in many rural and suburban districts, and therefore parents have no option but to send children to what are often insanitary dens. On this point the report of the Dublin Sanitary Association remarks: "It would seem that the Commissioners consider the attendance of the children as the essential thing; that, if convenient, this attendance should be in properly equipped schools; but if such schools are not provided, still the children must attend at any school, no matter how unsuitable it may be. We should rather interpret their duty to prohibit, as far as lies in their power, the attendance of children at any school which is not properly equipped." Not only, however, have parents to send children to unhealthy buildings, but they are bound, in case of the child's absence through illness, to produce a medical certificate of the cause. In cases of mild disorder, it is, of course, easier to send the child than to obtain the certificate, and in consequence children with various contagious diseases are found mixing with healthy children in the school-room and play-ground. There is no system of medical inspection of schools in Ireland, and the evils resulting from this indiscriminate mingling of the infective with the healthy consequently go unchecked.

*Infant Mortality in Dublin.*

A conference was held in the Mansion House, Dublin, last week to discuss the problem of infant mortality. The death-rate of infants under one year has been, on an average for the past five years, 146 per 1000, this being the highest rate in Ireland. The corporation has recently adopted the Early Notification of Births Act, and it is now proposed by the Women's National Health Association to organise a band of voluntary workers, who, under the control of the city health

department, are to visit the homes of the young mothers and offer advice as to the care of the babies. It is essential that these workers should be trained and efficient, and a committee of medical men, nurses, and others is already at work arranging a course of instruction. The movement has the support of the heads of the various maternity hospitals of the city.

*Dr. Macnaughton-Jones's Museum.*

With patriotic spirit Dr. Macnaughton-Jones has presented to the Royal College of Surgeons in Ireland his gynæcological museum. Though the collection is small—about 100 specimens—it is interesting, for Dr. Macnaughton-Jones preserved only objects of special pathological or surgical value. Moreover, the specimens are mounted so as readily to show these points of interest; they strengthen the museum of the College in a point where it was weak.

*The Royal Sanitary Institute.*

His Excellency the Earl of Aberdeen has consented to act as patron, and Lord Dunleath is to be the President, of the Twenty-sixth Congress of the Royal Sanitary Institute, which is to meet in Belfast, on the invitation of the city council, from July 24th to 29th.

*The Belfast Hospital for Sick Children.*

At the thirty-eighth annual meeting of the supporters of the Belfast Hospital for Sick Children (incorporated), held on Jan. 20th, the new president, Captain the Hon. Arthur O'Neill, M.P., occupying the chair, it was reported that during the past year 564 patients (261 medical and 303 surgical) had been treated in the wards, while in the out-patient department there had been 10,864 attendances. Financially, the expenditure for the year amounted to £1910 10*s.* 9*d.*, which was in excess of the income by £251. Dr. P. T. Crymble and Dr. W. McCready have been appointed members of the medical staff in place of Dr. B. O'Brien (resigned) and Dr. Joseph Nelson (deceased). The present class of students is larger than has been the case for several years.

Jan. 23rd.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*The Medical Treatment of Accidents to Workmen.*

THE *juge de paix* of the eighteenth *arrondissement* of Paris has recently decided a point of law which has remained uncertain until now, the question at issue being the payment of certain medical fees by the employer of an individual who had been injured in the course of his work. The point has now been decided in favour of the medical attendant. Some insurance companies had argued that fees for dressings, massage, and similar details of treatment were not due to the medical attendant unless the latter had personally carried out these procedures. The medical men, on the other hand, put forward the plea that these parts of the treatment, although not applied by them personally, were nevertheless conducted in their hospitals, under their direct supervision and on their responsibility, by the agency of nurses and other persons in their service, and that they were entitled to remuneration for these duties. As above mentioned, a decision was given in favour of the medical men.

*The Question of the Abortive Treatment of Syphilis.*

At a meeting of the Société de Médecine de Paris held on Jan. 13th, after a discussion in which M. Cayla, M. Gaston, and M. Leredde took part, a resolution, proposed by M. Druelle, was carried unanimously to the effect that the society, while fully recognising the meritorious endeavours which had been made to discover an abortive treatment of syphilis, was of opinion that this object had not yet been accomplished. At a recent meeting of the Société de Pathologie Exotique M. Nicolle and M. Conseil described some cases of malaria treated by "No. 606." They said that it produced a well-marked good effect very rapidly, causing an almost immediate improvement in the general symptoms, a fall of temperature, and a diminution in the number of the hæmatozoa. On the other hand, this action was neither complete nor of long duration. The remedy was indicated as the first step in the treatment of serious cases and ought to be followed by injections of quinine. The doses of "No. 606" administered under these circumstances were from 30 to 40 centigrammes.

*Seaside Bathing Resorts.*

At a meeting of the Société de Médecine de Paris held on Jan. 13th M. Levassort emphasised the importance of situation and the direction of exposure in connexion with sea-bathing quarters, saying that Brittany was the part of France which offered the most ample choice of bathing-places, according as a stimulant or a sedative effect was desired. By analogy with the methods followed at inland balneary resorts, he showed the advantage of immersing the legs, and spoke of the benefit which children derived from playing on the sand, although they also spent a portion of the day in the water. M. Froussard mentioned that in some mineral-water stations, especially at Plombières, foot-baths, leg-baths, and local douching of the lower extremities were employed every day for the relief of sanguineous congestion of the intestines and uterine appendages.

*Determination of the Freshness of Milk.*

The following method of determining the freshness or otherwise of milk was described by M. Bertin-Sans and M. Gaujoux at a meeting of the Pediatric Society held on Jan. 17th. The sample of milk contained in a test-tube had first added to it some drops of a red solution consisting of 0·25 part of fuchsine, 50 parts of alcohol, and 100 parts of water; some drops were then added of a blue solution consisting of 0·25 part of methylene blue and 1000 parts of water. The result was a violet colour which in fresh milk persisted for at least 24 hours, but in milk which was not fresh the colour turned to red with a rapidity proportionate to the change which the milk had undergone.

*The Association of Medical Students.*

At the general meeting which took place recently the Association of Medical Students approved the action of the committee with respect to questions of medical teaching. The association resolved to continue its efforts for the improvement of the professional education of students, and expressed regret that no reform had as yet been introduced by the public authorities. The association desires the creation of a superior medical council composed half of professors of the faculty and half of nominees of the medical syndicates, with the conferment of voting powers on medical students' associations. On the ground that the organisation of medical education requires a reform in the system of hospital attendance, the association also asks for an inquiry having for its object a modification of the appointment of *externe*, for which there ought to be an examination open to all students. The association considers that all medical students ought to have held this appointment for at least two years preparatory to obtaining the diploma of Doctor of Medicine.

Jan. 23rd.

## ITALY.

(FROM OUR OWN CORRESPONDENT.)

*Honours to Augusto Murri.*

THE Italian record in commemorative celebrations is a brilliant one, and yesterday's "Onoranze ad Augusto Murri" at Bologna more than maintained the national tradition. The occasion was the thirty-fifth anniversary of that distinguished consultant's lectures from the chair of clinical medicine, and it filled the theatre of the Ospedale di Sant' Orsola with an imposing audience, in which all the students of the present year and scores of old pupils, now professors or practitioners, were reinforced by the teaching staff of the University and by many citizens of both sexes. The proceedings opened with a few words of congratulation addressed to the master by one of the students, words full of the loyalty and affection which Professor Murri never failed to inspire; and then followed Dr. Floriano Brazzola, the lecturer on pathological anatomy, who, speaking for the Società Medica over which he presides, dwelt on the gratitude he and other old pupils felt towards their teacher, to whom they owed obligations which seemed to them to increase with advancing years. Professor Brazzola concluded by announcing the publication of a "Festschrift," to which he and others of the older "Murriani" will contribute in honour of their chief. After him came the President of the Association of the Medici Condotti (divisional or communal practitioners), who indicated the value

of teaching like Murri's in a *métier* such as theirs, where individual resource still responded to the lessons which at once moulded and inspired the *mens medica*. A touching tribute from Dr. Vitali, a colleague in the Senatus Academicus of Bologna, to the "twice-blest" teaching of the master, "happy for the giver as well as for the receiver," closed the official addresses, in acknowledgment of which Professor Murri, visibly affected, rose to reply. A rapid survey of the medical field as he found it and as he had helped to leave it led up to a loyal appreciation of his own masters, respect for whom was best shown, he said, by research and observation carried on in their spirit with all the improved aids that science and invention, checked by experience, were pressing into the service. The "metodo sperimentale," of which Bacon and Galileo were the pioneers, was at once the agency and the guarantee of sound thinking and sound practice, constituting the lines of a progress without limit, insomuch (he added, with a touch of humour and pathos) that the young minds he was addressing might, another 35 years hence, recall the celebration of to-day with the remark, "Come il nostro vecchio insegnante sapeva poco!" (How little our old teacher knew!) And so, amid repeated rounds of applause, the veteran clinician and consultant sat down, to receive, later in the day and at his own house, messages of congratulation, by post and telegraph, from correspondents grateful to him on various grounds, not only as a master of the healing art, but as a contributor to medical literature at home and abroad.

*The "Causa Causans" of Pellagra.*

Presiding to-day at the first meeting of the commission instituted by himself on the cause or causes of pellagra—a commission composed of Professor Lustig, its working president, with Dr. Alessandrini, Dr. Antonini, Dr. Bertarelli, Dr. Giannelli, Dr. Gosio, Dr. Sclavo, Dr. Tizzoni, and the Hon. Signor Caetani, as assessors—Signor Luzzatti, the Prime Minister, opened the proceedings with a retrospect of the findings of previous workers in that field. Lombroso's theory as to its cause residing in unsound maize is now abandoned, but on the strength of that theory greater attention was paid to the conditions, dietetic and other, under which the agricultural labourer lived, and the result was, undoubtedly, a marked decrease in the mortality, particularly in the cases of lunacy due to pellagra—7·9 per cent., the proportion of such patients in asylums in 1898, having sunk to 3·5 per cent. in 1908. Tizzoni, holding Lombroso's theory to be untenable, ascribed the disease to a specific bacillus which he called the "strepto-bacillus pellagræ." This did not satisfy Alessandrini, who found the cause in a parasite infecting the surface of the potable water drunk in the fields, while Sambon traced it to the puncture of a minute insect which he designated the Simulium reptans. This finding seems to command pretty general favour, in accordance with which the commission is prosecuting its researches into the required prophylaxis and cure. Meanwhile it maintains the subsidiary measures introduced by Lombroso (the improved alimentation secured by "cucine economiche," *inter alia*) and the general amelioration of the conditions under which the rural population lives and labours.

Jan. 20th.

## VIENNA.

(FROM OUR OWN CORRESPONDENT.)

*The Reward of Medical Honesty.*

A FEW months ago an unexpected result followed the notification of a case of typhoid fever by a country practitioner acting also as district medical officer in a village near Linz, Hungary. On discovering the patient he at once notified the disease, as he was, in fact, bound to do, and in this case the duty of notification was exceptionally imperative as military manœuvres were about to take place in the district and a camp was to be formed in the village in question. In consequence, however, of the presence of the disease being notified to the military headquarters the camp was not formed there and the inhabitants lost the opportunity of selling articles of various kinds to the officers and soldiers. It could not be proved that they had sustained any actual financial loss because they had not made any special provision for the occasion, but nevertheless there was general indignation against the district medical officer, and this feeling was fostered until he was practically boycotted by the population. He and his household were even refused food and clothing in the village and the lives of the members of his family were endangered. Protests made by him were useless; he not only received no protection from the local authorities, who felt themselves aggrieved by the notification of the infectious case, but he was even dismissed from his appointment as district medical officer. In vain all the medical corporations tried to induce the population to take a reasonable view of the circumstances, but nothing would satisfy them short of the expulsion of the unfortunate man from the place. The medical organisation then issued a warning to prevent any other practitioner from settling there, as it was hoped that after some time the animosity of the villagers would subside, and in the meantime all endeavours were made to induce the Government to give an authoritative decision to the effect that the medical officer could not be blamed for having done his duty. But the worries and excitement of such a complicated situation, and the dread of losing his only means of livelihood, proved too much for the victim of this persecution, who was suddenly cut off by an attack of cardiac paralysis. The affair, however, is not at an end, because in medical circles an endeavour will be made to obtain substantial damages for the family of the wronged medical officer.

*Midwives in Vienna.*

The unsatisfactory position of the midwives in this city has for a long time been a burning problem for the sanitary authorities. One of the most frequent complaints is that overcrowding of this particular occupation is nowhere so manifest as here. For instance, whilst in Berlin with its larger population there are only 800 authorised midwives, in Vienna there are over 2000. This was pointed out a few years ago in a mass meeting of midwives, in which the speakers demanded the institution of a *numerus clausus* for their occupation, for under the present conditions there were many trained midwives in the city who had not one case of labour to conduct in a year. In the country districts the rate of payment was so bad that no woman of the better class cared to undertake the duties. The "midwife tariff," as it is called, stipulates a fee of approximately half a sovereign for an attendance of 10 days, including the delivery; this tariff has existed since the year 1845 and urgently requires revision. The insufficiency of the earnings of the city midwives naturally prompts many of them to undertake procedures of a criminal nature. As a rule, the poor women in this city prefer to go to one of the numerous hospitals for their lying-in, whilst the middle and upper classes always require the presence and active help of a gynæcologist and afterwards that of a surgical nurse. The total number of births is also steadily diminishing, whilst the number of midwives is increasing. This question therefore calls for reform.

*Health of Vienna Labourers.*

In the winter months there is usually an increase of illness among special sections of the population, and principally among the poorer members of the working-classes, a circumstance which is plainly shown by the report of the Krankencassa (sick club) of labourers, dealing with the health of its 310,000 members. In November and December, 1910, there were respectively 8995 and 8886 cases of illness incapacitating for work. Of these there were in November 793 and December 760 cases of illness caused by tuberculosis of the respiratory organs, whilst other diseases of these organs numbered 1364 in November and 1479 in December. In November there were among club patients 427 cases of tonsillitis, 312 cases of influenza, 287 cases of disorder of the circulatory organs, 522 cases of severe gastro-intestinal diseases, 803 cases of rheumatism, and 1766 cases of accident or injury. In December there were 327 cases of tonsillitis, 349 of influenza, 292 of disorder of the circulatory organs, 629 of severe gastro-intestinal disease, 793 of rheumatism, and 1908 of accident or injury. All the cases included in these returns were sufficiently severe to confine the patient to bed for at least three days. The mortality was nearly 3 per cent. of the patients, which compares well with the mortality in our general hospitals, where it is from 8 to 10 per cent. of the inmates, whilst the general mortality for Vienna

is 15 per 1000. Fully one-third of all deaths were due to tuberculosis of the lungs or larynx, whilst the other deaths due to disease of the respiratory organs only amounted to 6 per cent. The mortality due to circulatory disease was also high, being 22 per cent., whilst neoplasmata claimed 8 per cent. of the deaths. Of the cases of accident or injury 3 proved fatal in November and 7 in December, the aggregate mortality under this heading being about 0·33 per cent.

## NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

*The Indian National Congress and Medical Problems.*

THE Indian Medical Service came in for discussion at the Indian National Congress on Dec. 28th. Sir Balchandra Krishna moved a resolution requesting the Government of India to take early action in the direction pointed out by the Secretary of State regarding the employment of independent medical practitioners in the superior posts of the civil branch of the Indian Medical Service. The resolution also urged the constitution of a distinct Indian civil medical service wholly independent of the Indian Military Medical Service. The Indian Medical Service was created for the Indian army was the view forcibly brought to the notice of the members of that service by its Director-General. In the same speech the Director-General reminded the Indian Medical Service officers of the necessity of creating a better feeling between themselves and the officers of the Royal Army Medical Corps, and also between themselves and the general practitioners. Such words from one in his position go far to suggest that the time is approaching when an Imperial Army Medical Service may be organised, whose officers will do duty only in connexion with the army, a civil medical service as well as a separate sanitary service being also instituted.

*A Sanatorium for Consumptives in the United Provinces.*

A sanatorium for consumptives was the form decided upon for the United Provinces memorial to His late Majesty the King-Emperor at a representative meeting of official and non-official gentlemen at Allahabad held recently, presided over by the Lieutenant-Governor. This scheme, which is favoured by Sir John Hewett, is likely to receive very general support. A technological institute and a provincial orphanage have been mentioned as two alternative schemes, but owing to various difficulties that might arise in attempting to execute them they received no support at the meeting, which unanimously agreed to the sanatorium for consumptives. An influential committee was appointed to collect subscriptions and carry out the arrangements.

*Courses of Instruction for Indian Medical Service Officers.*

The Government of India has concurred in a proposal of its Sanitary Commissioner that the course of training in clinical bacteriology and technique at the Central Research Institute, Kasauli, for officers belonging to the Indian Medical Service (but not serving under the bacteriological department) should last for four weeks. Officers selected to attend this course will be permitted to be absent from their stations for this period, in addition to the actual time occupied by the journey to and from Kasauli and one day for preparation for each journey. The classes of instruction will in future assemble in the months of January, March, May, July, September, and November each year. No officer drawing allowances from local funds will, however, be allowed to proceed to Kasauli for a course of training in clinical bacteriology and technique unless he is prepared to forego those allowances or unless the local fund authorities agree to pay these allowances both to the officers permitted to go to Kasauli and to the officers appointed to act for them. In all other cases he will be entitled to retain any local allowance drawn by him immediately before he proceeded to Kasauli without prejudice to the claims to such allowance of the officers acting for him.

*Medical Students at Lahore.*

Among the colleges in Lahore, and affiliated to the Punjab University, the Medical College is the only one which is unprovided with a hostel or boarding-house. The Syndicate of the Punjab University considered recently a letter on this subject from the Inspector-General of Civil Hospitals, who had suggested that the University should insist either upon all medical students who could be accommodated living in hostels, or upon first- and second-year students doing so. The Syndicate was of opinion that any such rule should be made by the College rather than by the University, that the charge proposed was higher than in any other college in Lahore, and that in view of the changes to be made in connexion with the King-Emperor Edward VII. memorial scheme the question of hostel accommodation might stand over for the present.

*The Status of Assistant Surgeons and Sub-Assistant Surgeons.*

Mr. Robertson, Secretary to the Government of Bombay, replying to the resolutions regarding the registration of medical practitioners in India, which have been laid before Government, states:—

With reference to the opinion that military assistant surgeons and civil medical assistants (now styled sub-assistant surgeons) should not be classed as duly qualified medical practitioners for purposes of medical registration, I am to observe that Government have for many years educated two classes of medical practitioners, primarily for their own departments, and have received them into their service as military assistant surgeons and civil medical assistants on their undergoing a fixed course of training under competent teachers at certain medical schools and colleges. No "licence" or "diploma" has been granted to these men, but they have been given by Government all the privileges of qualified medical practitioners and have performed, as part of their routine work, all duties which could have been demanded of them had their qualifications been of the highest. The Governor in Council therefore does not agree in the opinion expressed by the meeting that members of both these classes, who have received regular training on Western lines and passed the recognised tests, should be regarded as "unqualified," and classed with vaids, hakims, Ayur Vedic doctors, apothecaries, &c. Government is not aware how far the views communicated by you are shared by the rest of the medical profession in the city of Bombay, but the fact that these two classes of men were included by the Bombay branch of the British Medical Association in the committee appointed by that body to consider the question of registration appears to be a strong evidence that the most influential medical men of Bombay are not in sympathy with the opinion expressed at the meeting. I am to add that in all countries the sole authority which lays down the conditions constituting qualifications for the legal practice of medicine and surgery is Government, and that after carefully considering the views expressed in your letter and the resolutions accompanying it, the Governor in Council sees no reason to exclude military assistant surgeons and civil medical assistants from the proposed registration of duly qualified medical practitioners. Other points touched upon in the resolutions will be duly considered by Government when the proposal to pass the Registration Act comes before them.

*Retirement of Colonel J. Shearer, C.B., D.S.O., I.M.S.*

The last *Gazette of India* contains the notification of the retirement from the service of Brevet-Colonel J. Shearer, Principal Medical Officer of the Derajat and Bannu Brigades. This officer has had a long and distinguished career in India and has seen much active service, including the Egyptian Campaign of 1882, the war in Burma 1887–8, Hazara Expedition 1891, Miranzai Expedition 1891, Waziristan Expedition 1894–5, and Tirah Expedition 1897–8. Colonel Shearer was for some time secretary to Sir Thomas Gallwey K.C.M.G., C.B., when Principal Medical Officer, His Majesty's Forces in India, and was closely associated with the far-reaching administrative reforms carried out by this officer during his tenure of appointment under Lord Kitchener. Colonel Shearer's retirement will be a great loss, not only to the Indian Medical Service, but to Freemasons throughout India, as he has done much to promote the interests of the craft in this country in which he filled various high offices with distinction.

*Dr. C. A. Bentley.*

It is understood that on the termination of his present appointment under the Bombay Government, Dr. Chas. A. Bentley, who has been doing special work on malaria, will be appointed Deputy Sanitary Commissioner of Eastern Bengal and Assam.

Jan. 5th.

## NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

*Vital Statistics.*

RECENT vital statistics show a steady decline in the birth-rate, but New Zealanders may take some comfort in that while the births are few the rate is higher than it is in Australia. The average number per family for the ten years, 1890–99, showed 4·22 births per marriage, while for the period 1900–09 it was 3·22. It would appear that 46 out of every 1000 children born were born out of wedlock. In these

cases more than half the mothers were under 23 years of age. Five were 14 years of age, 9 were 15 years, 34 were 16 years, 63 were 18 years, 146 were 19 years, 101 were 20 years, 103 were 21 years, 85 were 22 years, and 89 were 23 years of age. According to the Registrar-General, the expectation of life for males is 54·44 years. It would appear that the influence of the Chinese consul is making for less restrictive measures with respect to the admission of immigrants from China. At present, in addition to a poll-tax of £100 every Chinaman had before admission to read and write some sentences in a European language. By a Government Bill introduced recently, the Governor takes power to modify these conditions. It must not be presumed from this, however, that there will be any relaxation in the campaign in favour of a white New Zealand. From the report of the inspector of mental hospitals it would appear that there are 3549 people in these institutions. This means that one in every 280 of the people of New Zealand is insane. The proportion is, perhaps, slightly greater because there are some who are looked after by their friends. The ratio would appear to have increased since last year. Males show 1 in 253, females 1 in 318. As to the causes, heredity seems to be responsible for 14·36 per cent.; critical periods, 14·2 per cent.; mental stress, 9·6 per cent.; while alcohol is credited with only 4·9 per cent. The average gross cost per head is £34 13*s.* 3½*d.*

*Vaccination.*

The same tale has to be told with respect to vaccination. Only some 4·3 per cent. of the children born last year were vaccinated. The steady decrease in the number of the children protected is a matter for grave concern, but, alas, those in authority pay little attention. An amendment to the Public Health Act was introduced by the Government towards the end of last session, but, like many others, it would seem only to have found a place on the order paper so that it might form one of the "innocents" yearly thrown to sacrifice. The proposal was practically to delete all semblance of compulsion from the Act governing vaccination, but in case of small-pox appearing in any part of the Dominion the Governor was to have power to declare an "infected area," and to require all inside that area to be vaccinated. At the present time the law is practically a dead-letter, and to allow it to remain upon the statute book and not to enforce it is wrong. It should be remembered that the disobedience to the law is the result of carelessness rather than any active opposition, although there are, of course, the section who are continually declaiming against the interference with "personal rights."

Dec. 19th, 1910.

## UNITED STATES OF AMERICA.

**(FROM OUR OWN CORRESPONDENTS.)**

*The Society of Sanitary and Moral Prophylaxis.*

THE object of this society is to endeavour by all possible means to decrease the spread of venereal diseases. Dr. Prince A. Morrow is the president of the society. The society includes in its membership prominent members of the medical profession, as well as laymen and laywomen of note. A public meeting of the society was held in the New York Academy of Medicine on Dec. 22nd, 1910, and was largely attended, the majority of the audience being women, Dr. Morrow being in the chair. An address was delivered by Professor E. R. A. Seligman of Columbia University on the sanitary supervision of prostitutes. It was a vigorous criticism of the Payne Bill passed recently in the State of New York, with a view of checking venereal diseases by partial measures for regulating prostitution. Much opposition has been developed against the Bill, especially against Clause 79 for the sanitary supervision of prostitutes. There is a great aversion in this country to any kind of regulatory measures, and in his address Professor Seligman gave expression to this sentiment in strong terms. Furthermore, the argument was brought forward that the Payne Law is not far-reaching enough to be of any use. At any rate, there can be little doubt that the systems of regulating prostitutes in vogue in Europe will not meet with favour in this country. Dr. Stephen Smith, the Nestor of the medical profession in New York, and one of the pioneers of the New York Board of Health, read a paper on the powers of the health board to control venereal disease. He pointed out that these powers are arbitrary, almost autocratic, and that therefore sufficient authority is vested in this board to deal with the matter as its members may think fit, and that, so far as New York City is concerned, the board of health is perfectly competent from all points of view to meet the situation. Dr. A. Jacobi, Dr. Darlington, and several others joined in the discussion, but the trend of all the speeches was in opposition to the regulation of prostitution as a means of controlling venereal diseases. The society itself does much, and hopes to do much more, by educative means, by the distribution of literature, and by lectures delivered in all parts of the country. The most interesting feature of the present widespread campaign in America against venereal disease is the manner in which everywhere the matter is publicly discussed. Not long ago the subject was entirely tabooed. Now public meetings are held, at which women, not only mothers of families but even girls, are present, where sexual hygiene and venereal diseases are made the subjects of free and open debate.

*Preventable Insanity.*

A meeting of the New York State Charities Association at the New York City Academy of Medicine on the evening of Dec. 23rd passed resolutions to the effect that fully 70 per cent. of the cases of insanity received into our asylums are preventable, and that an immediate campaign of education should be instituted among the people. Among the 70 per cent. of preventable cases the association classed those induced by alcohol and drug habits, by various infections, auto-intoxications, emotional strain, and overwork. During the past decade, while the population of New York State has increased less than one-half, the number of known cases of insanity has doubled. Last year 6400 new cases were admitted to the asylums, a net increase of 1200. Much of this increase is apparent, however, owing to improved methods of diagnosis and to more attention being paid to the insane.

*The Plea of Insanity in Murder Cases.*

The Society of Medical Jurisprudence of New York City at a recent meeting has discussed the question of the frequent escape of murderers from capital punishment on the plea of insanity. At present juries are obliged to acquit prisoners adjudged insane. The society recommended a change in the law so that a verdict might be rendered "guilty but insane," which would lead to the immediate incarceration of the prisoner in an asylum for the criminal insane, but would not absolve him from the usual penalty if he should at some future time regain his reason. A distinction would thus be established between insanity at the time of the commission of a crime and insanity at the time of trial, and the latter would not save the life of a prisoner adjudged guilty if he finally recovered. Doubtless the death penalty would never be exacted in such cases.

*The Cost of Hospital Patients in New York.*

In announcing the Hospital Saturday and Sunday collections this year the association in charge thereof has drawn attention to the fact that in ten years the cost of treating a patient has incresed 100 per cent. In 1900 the daily cost of each patient was 4*s.* 10½*d.*, whereas to-day it amounts to 8*s.* 10*d.*

*The Federal Government and the Rotten Egg Traffic.*

The Federal Government is prosecuting several firms for selling to bakers eggs in an advanced stage of decomposition, to which practice I referred in THE LANCET of Jan. 7th, p. 66. Such eggs have a legitimate market among manufacturers of varnish, but bakers have been purchasing them at nearly ten times the regular market price. It appears that the hydrogen sulphide disengaged from such eggs is used in place of carbon-dioxide in raising bread and cake. They have been sold in bulk by the pound, the shells being discarded and formaldehyde added to the putrefying mass of yelks and whites, which is then frozen and disposed of in that condition. An analysis of this precious mess showed 8,000,400,000 micro-organisms to the cubic centimetre.

*Exercise for Naval Officers.*

The famous Roosevelt "tests" for officers of the navy have been abolished, and the new regulations demand only a quarterly exercise by officers of the navy and public health

and marine hospital service. They will be obliged to walk 25 miles in two consecutive days, five consecutive hours being allowed for each day, and the walk of 12½ miles each day is not to be completed in less than four hours. Physical examinations will precede and follow each test, and officers found unfit will be ordered before a retiring board.

*Naval Dental Officers.*

The Congressional House Committee on Naval Affairs has recently reported favourably on a Bill entering members of the dental corps as acting assistant surgeons, with provision that after 11 years' service there may be developed from them automatically one lieutenant-commander, four passed assistant surgeons, and 25 assistant surgeons.

*Smoking Automobiles.*

Federal legislation is being sought for protection of the pedestrian public against smoking automobiles, which have become veritable nuisances everywhere, and a probable menace to health.

# Obituary.

## HENRY POWER, M.B. LOND., F.R.C.S. ENG.,

LATE VICE-PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; AND CONSULTING OPHTHALMIC SURGEON TO ST. BARTHOLOMEW'S HOSPITAL AND THE WESTMINSTER OPHTHALMIC HOSPITAL.

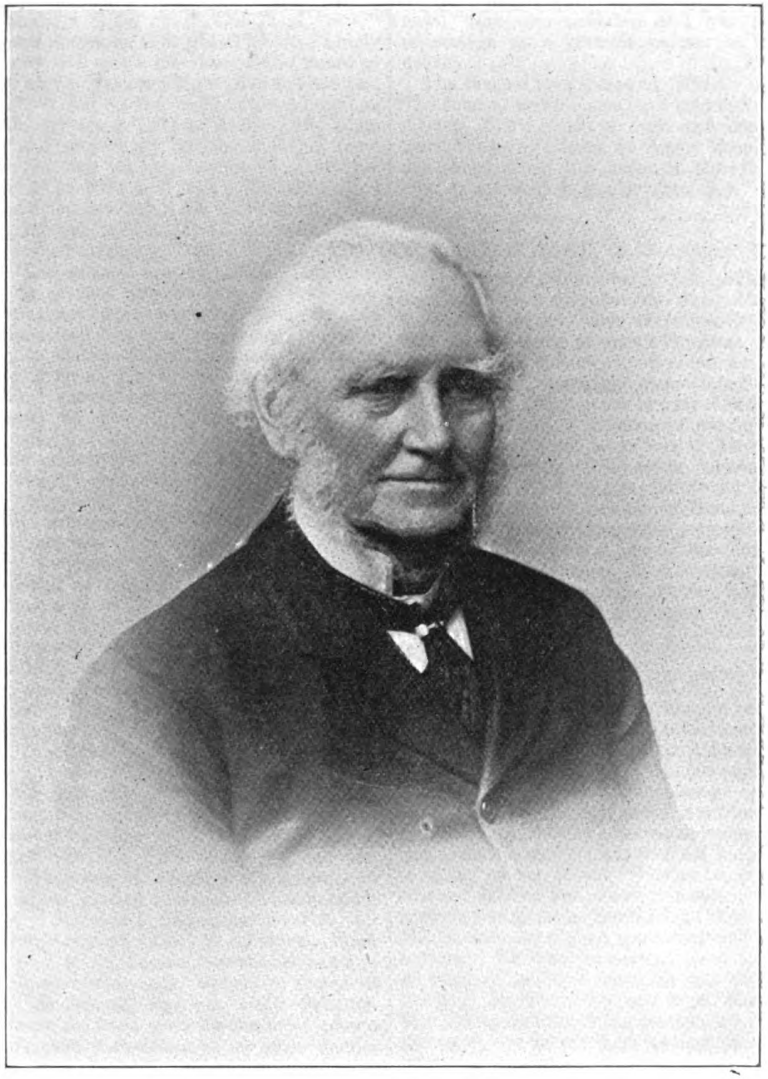
WE deeply regret to announce the death of Mr. Henry Power, consulting ophthalmic surgeon to St. Bartholomew's Hospital, and for more than 40 years a regular member of the staff of THE LANCET, the sad event having occurred at his residence, Bagdale Hall, Whitby, on Wednesday, Jan. 18th.

Henry Power was born at Nantes in France on Sept. 3rd, 1829, the only child of Captain John Francis Power by his second wife Hannah, daughter of Mr. Henry Simpson, of Meadowfield, Whitby, Yorkshire. His father came of a long line of soldiers, and received his first commission at the early age of 14 years. He served through the Peninsular, Baltic, and Waterloo campaigns, and received the Peninsular medal (1793–1814), with a clasp for Sahagun and Benevente, as a cornet in the 3rd Dragoons King's German Legion, and the Waterloo medal as a lieutenant in the 3rd Regiment of Hussars K.G.L. He was afterwards captain and major in the 35th (Royal) Sussex Regiment, "the Old Orange Lilies," and at the time of his death in 1856 he was lieutenant-colonel in command of the British Foreign Legion at Shorncliffe. Immediately after his birth Henry Power was taken to Barbados, where his father was quartered, and narrowly escaped death in the hurricane which devastated the island on the morning of August 11th, 1831, when the barracks were blown down, killing the sergeant-major, a sergeant, and five privates. Major Power resigned his commission in 1833, and for many years spent the wandering life which was then usual with half-pay officers who had no private means. His son, therefore, was educated for short periods at schools in Gloucester, Liverpool, Cheltenham, Leamington, and Whitby, never remaining long enough at any place to receive a thorough grounding in classics and mathematics. His name appears in the lists of Cheltenham College as a day boy admitted at Easter, 1842, the college having been opened in the previous autumn. Having decided to adopt the profession of medicine, he was apprenticed to Mr. Thomas Lowe Wheeler in 1844, who was afterwards chairman of the Board of Examiners at the Apothecaries' Hall. Mr. Wheeler was the son of Thomas Wheeler (1754–1847), the botanist, who was apothecary to St. Bartholomew's Hospital. The apprentice lived with his master in Newcastle-court, Gracechurch-street, E.C., entered St. Bartholomew's Hospital, and was diligent in attending the early morning botanical lectures and the herborisings which were then a feature of the medical curriculum.

The result of this botanical training enabled Mr. Power to win the Galen silver medal and the Linnæan silver medal given annually by the Society of Apothecaries, and in 1851 he was admitted a Licentiate of this body. In the same year he took the Membership of the Royal College of Surgeons of England, and on Dec. 1st, 1854, he was elected F.R.C.S. Eng. At the same time he was graduating in medicine at the University of London where he had a brilliant career. He took the prize in chemistry at the matriculation examination, the exhibition and gold medal in anatomy and physiology, and the gold medal in structural and physiological botany at the intermediate examination in medicine in 1852, the scholarship and gold medal in physiology and comparative anatomy, and the scholarship and gold medal in surgery at the Final M.B. examination, graduating M.B. in 1855. Four years before, that is in 1851, he had been appointed demonstrator of anatomy at the Westminster Hospital, and for the next ten years he lectured successively on comparative anatomy, human anatomy, and physiology at that school. He was appointed assistant surgeon to the Royal Westminster Ophthalmic Hospital in 1856 and assistant surgeon to the Westminster Hospital in 1857. The latter post he resigned in 1867, when he was elected ophthalmic surgeon to St. George's Hospital. In 1870 he resigned his position at St. George's Hospital to become the first ophthalmic surgeon at St. Bartholomew's Hospital, a position which he held for nearly a quarter of a century. For 12 years he was ophthalmic surgeon to St. Bartholomew's Hospital at Chatham, where he attended every Wednesday afternoon, leaving London at 2 o'clock and arriving in town again at 6, and as by this time his private practice was very large, it will be seen that throughout his long professional career his life was an extraordinarily industrious one.

Mr. Power's varied literary work showed well his industry and wide range of exact knowledge. In 1863 he translated for the New Sydenham Society the work of Wilhelm Kramer of Berlin, entitled: "The Aural Surgery of the Present Day." From 1864 to 1876 he edited the sixth, seventh, eighth, and ninth editions of Carpenter's famous "Principles of Human Physiology." The following excerpt from a review of the seventh edition, published in THE LANCET of April 10th, 1869, bears testimony to the essential characteristics of his work: "It is in all respects an admirable work, and we congratulate Dr. Carpenter on having secured the services of a man endowed with the ability, learning, and conscientious exactitude of its editor, Mr. Power. We almost regret, with so much new matter on the one hand, and the recasting and reconstruction of the old on the other, that Mr. Power did not rewrite the book, for the production of a new edition so complete as the present one must have caused him infinite labour." As a matter of fact, Power may almost be said to have rewritten each edition. In 1869 "Illustrations of the Principal Diseases of the Eye" was published by Messrs. Churchill, the original coloured drawings having been made by Power himself from the patients who came under his observation at the Royal Westminster Ophthalmic Hospital. In 1870 he translated for the New Sydenham Society Professor Stricker's "Manual of Human and Comparative Histology." This publication formed a very valuable and welcome addition to English medical literature. The translator's own knowledge of the subject, joined to his familiarity with the German language and his mastery over his own, resulted in the production of a volume that betrayed scarcely a trace of its foreign origin. In 1876 Power translated, for Ziemssen's "Cyclopædia of the Practice of Medicine," Erb on "Diseases of the Peripheral Cerebro-spinal Nerves," and from 1879 to 1899 he re-edited, for the New Sydenham Society, in conjunction with Dr. Leonard Sedgwick, Mayne's "Expository Lexicon of Medical Terms." The new edition was planned on so large a scale, that the last volume, P to Z, was completed by Mr. George Parker. In 1884 his "Elements of Human Physiology," one of Cassell's manuals, was published, was very highly commended by the medical press, and obtained wide popularity.

When it is remembered that in addition to all his literary and official duties Mr. Power was for many years a leading London ophthalmic surgeon whose wise advice and manual dexterity were daily in demand, it will be wondered what time over he could have to place at the disposal of this journal. The fact is that he was an untiring as well as a methodical worker, and his industry and love of order enabled him not only to keep abreast of ophthalmological literature, but also to read widely in anatomy, physiology, and botany, and to record his candid views upon what he read with regularity. Week after week, year after year, in this manner he sat in genial judgment upon medical writers, and so closely accurate were his appreciations, and so obviously fair and friendly his strictures, that we can hardly remember an occasion when an author was moved to protest against his criticisms. Gradually, as different



HENRY POWER, M.B. LOND., F.R.C.S. ENG.,

LATE VICE-PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; CONSULTING OPHTHALMIC SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

branches of science underwent development, Power advised us that it was time for us to seek the help of some one more in touch with special work in zoology, botany, and, lastly, in physiology; but for many years in these subjects as well as in his particular subject of ophthalmology he was our general adviser. No member of the staff was ever more missed than he was when retirement from London broke his intimate association with us, and in this office his memory will always be cherished. And the feeling of regret that we can thus personally express will, we know, be shared by hundreds of his colleagues, pupils patients, and friends, for it was impossible not to feel that Power's handsome presence and genial bearing were the exterior that fitted well a generous, simple, strenuous nature.

At the Royal College of Surgeons of England he filled nearly all the official positions. He was a member of the Board of Examiners in anatomy and physiology from 1875 to 1880 and again from 1881 to 1884, and on the reconstituted board as an examiner in physiology from 1884 to 1886, and as an examiner in anatomy and physiology for the F.R.C.S. from 1884 to 1886. He served two terms of office as a member of the Council from 1879 to 1890, and was a Vice-President for the year 1885. He delivered the Arris and Gale lectures on Anatomy and Physiology, 1882–83; was Hunterian Professor of Surgery and Pathology, 1885–87; Bradshaw lecturer, 1886; and Hunterian Orator in 1889. His wide learning, his particularly clear insight into his subjects, and his kindness of heart and manner made him an ideal examiner. He acted as an examiner in physiology at the University of London in 1870, as examiner in the natural science tripos at Cambridge in 1874–75, as examiner in the school of natural science at Oxford 1875–77, and he also examined at the University of Durham. Among other posts which he filled may be enumerated the office of professor of physiology at the Royal Veterinary College 1881–1904, where he became the friend and trusted adviser of many generations of veterinary students. On his retirement he was much touched by their presentation to him of an arm-chair fitted with an electric reading-lamp and furnished with an appropriate inscription, as well as by a separate presentation from the veterinary surgeons in South Africa who had been too late in joining the original testimonial. He served the office of President of the Harveian Society of London for a double term of office during the years 1880–81, a unique tenure of the chair. He was President of the Ophthalmological Society of the United Kingdom 1890–92; Bowman lecturer in 1887, when he took for his subject "The Relation of Ophthalmic Disease to Certain Normal and Pathological Conditions of the Sexual Organs"; and a Vice-President of the Royal Medical and Chirurgical Society 1892–93. For many years he was surgeon to the Linen and Woollen Drapers' Benevolent Fund and to the Artists' Benevolent Society.

He married his first cousin Ann, daughter of Mr. Thomas Simpson, of Meadowfield, Whitby, Yorkshire, on Dec. 21st, 1854, with whom in due course he celebrated his golden wedding day. He lived immediately after his marriage at 3, Grosvenor-terrace, now 56, Belgrave-road, S.W.; in 1866 he moved to 45, Seymour-street, W.; and in 1870 to 37a, Great Cumberland-place, where he remained until he retired to his house, Bagdale Hall, Whitby. Always a hard worker, as we have seen by our brief record of his professional life, the necessities of a large family made the earlier years of his life especially strenuous. Coaching students for their examinations and literary work were the chief sources of income, and for many years he accustomed himself to go to bed at two or three o'clock in the morning and to awake at six, when he was ready to go to the baths with his boys or to the parks for a run before breakfast, or in later years for a bicycle ride. Many pleasant evenings were spent with T. K. Parker at a time when he was working first on the foraminifera, later on the shoulder girdle and sternum in the vertebrata, and, finally, on the structure and development of the frog's skull. Parker's beautiful dissections made with a pair of sewing needles stuck into penholders and his harmless eccentricities of expression and of thought were a constant theme of wonder and amusement, and his death was the first of a series of blows which saddened the later years of Mr. Power's life. Sir William Savory, his life-long friend and companion, died in 1895; Mr. Bowater J. Vernon, his colleague with whom he was in daily communication, in 1901; and the dreadful tragedy when his artist daughter and his granddaughter were drowned before his eyes and he was himself rescued with difficulty finally decided him to leave London for a more restful life in congenial surroundings.

Mr. Power was a skilful artist both in water colours and with a brush and indian ink, and in early life he played the violin. His artistic powers he inherited from his father, who had received a commission from H.R.H. the Duke of York in return for a pair of water-colour sketches which he had ventured to send as a present to the Commander-in-Chief with a letter asking for employment as the son of a Peninsular veteran. These powers he transmitted to one daughter—Lucy Beatrice—who exhibited at the Royal Academy on more than one occasion and was making for herself a reputation as a portrait painter at the time of her tragic death.

The funeral took place at Whitby on Saturday, Jan. 21st. The funeral service was read impressively by the Rev. George Austen, M.A., canon of York and rector of Whitby. There were numerous tokens of regard from his fellow townsmen, the shops along the route of the funeral being nearly all closed, although it was market day.

---

### THOMAS FULLER, M.D. ABERD., M.R.C.S. ENG., L.S.A.

Dr. Thomas Fuller died at his residence, Penryn, Wilbury-avenue, Hove, Brighton, on Jan. 13th, at the age of 83. Born at the county town of Lewes in Sussex, he received his medical education at Guy's Hospital, qualifying as M.R.C.S. and L.S.A. in 1851. He obtained his M.D. degree at King's College, Aberdeen, eight years later. Settling at Shoreham he founded a large practice over a wide area of the Steyning Union and held a number of public appointments, among them that of medical officer of the workhouse, surgeon to the Royal Artillery, Shoreham Redoubt, Admiralty surgeon and agent for Shoreham; while at one time he was house surgeon at the Sussex County Hospital, Brighton, and house surgeon at the Brighton Dispensary. He took a very active interest in the public life of Shoreham, which he left some 15 years ago on retiring from medical practice. The funeral took place in Shoreham churchyard on Dec. 18th amid manifestations of the deepest sorrow and regret.

---

### BANFIELD TEAGUE VIVIAN, L.S.A. LOND.

Mr. B. T. Vivian died at his residence, Buckshead, Hayle, Cornwall, on Jan. 13th, in his ninetieth year. The deceased, who was the oldest medical practitioner in Cornwall, was the son of the late Dr. John Vivian of Crowan, Cornwall. He received his medical education at the Charing Cross Hospital and Hunter's School of Anatomy, and qualified L.S.A. in 1848. He shortly afterwards joined his father in practice at Crowan. Mr. Vivian was for more than 50 years district medical officer to the Helston Union. He took a great interest in the Volunteer movement and was at one time honorary surgeon to the old 1st Cornwall Volunteer Artillery. Mr. Vivian was a good sportsman and an authority on horticulture. He was unmarried, very popular, and during his 63 years of medical work he was always extremely kind to the poor, by whom he was much beloved. By the death of Mr. Vivian an interesting personality has been removed from Cornwall, for in his time he had a very large and extensive practice.

---

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Karl Friedrich Mosler, who retired from the chair of clinical medicine in the University of Greifswald about a dozen years ago. Soon after qualification, when assistant in the Giessen Medical Clinic, he worked under Professor Leuckart, the eminent zoologist, at human parasitology, and amongst his various writings several of the most noteworthy deal with this subject. He contributed (in conjunction with Dr. Peiper) the article in "Nothnagel's Handbook" on Animal Parasites and that on Diseases of the Spleen in "Ziemssen's Handbook." He was in his eightieth year.—Dr. Wilhelm Koenig, formerly senior physician to the Dalldorf (in Prussia) Lunatic Asylum, from which post he had been obliged to retire some years ago on account of ill-health. His age was 52 years.

# Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated :—

*Surgery*.—M. J. A. Des Ligneris (Sections I. and II.), Berne; and B. W. Loewenberg (Sections I. and II.), Berlin and London Hospital.

*Medicine*.—G. J. F. Elphick (Sections I. and II.), St. Mary's Hospital; B. W. Loewenberg (Section II.), Berlin and London Hospital; and F. G. Norbury (Section I.), Glasgow.

*Forensic Medicine*.—N. S. Adler, Berlin; J. Ellison, Cambridge and St. George's Hospital; and R. G. Maglione, Manchester.

*Midwifery*.—A. J. V. Mathews, St. Mary's Hospital; and H. Rowntree, Middlesex Hospital.

The Diploma of the Society was granted to the following candidate, entitling him to practise medicine, surgery, and midwifery: B. W. Loewenberg.

FOREIGN UNIVERSITY INTELLIGENCE.—*Breslau:* Dr. Lothar Dreyer has been recognised as *privat-docent* of Surgery, and Dr. Walter Oettinger as *privat-docent* of Hygiene.—*Cairo:* Dr. Schmidt, of the Chemical Department of the Medical School, has been granted the title of Professor by the Prussian Government.—*Genoa:* Dr. Pietro Baiardi has been promoted to the chair of Ophthalmology.—*Halle:* Dr. Alfred Denker, Professor in Erlangen, has accepted the chair of Otology in succession to the late Dr. H. Schwarze.—*Jena:* Dr. Bodo Spiethoff, *privat-docent* of Dermatology, and Dr. Wilhelm Strohmayer, *privat-docent* of Psychiatry and Neurology, have been appointed Extraordinary Professors. Dr. Rehn of Königsberg has been recognised as *privat-docent* of Surgery.—*Messina:* Dr. Arturo Donaggio has been promoted to the chair of Neurology and Psychiatry.—*Rostock:* Dr. H. Reinmöller, *privat-docent*, has been appointed Extraordinary Professor of Odontology.—*Stuttgart:* The Veterinary College has been authorised to grant the degree of Doctor of Veterinary Surgery.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Jan. 19th, Sir Francis Champneys being in the chair. The difficulties experienced by local supervising authorities in obtaining convictions under Section 1 (2) of the Midwives Act, 1902, led the Board to suggest to the Privy Council the desirability of amending the Midwives Act, 1902, Section 1 (2), by omitting the words "habitually and for gain," with a view to the more effective administration of the Act. In reply to an inquiry from the medical officer of health of Sheffield as to the extent of a midwife's obligation to visit her patient during the puerperium, the Board stated that it had designedly refrained from making it obligatory on the midwife in every case to attend her patient for ten consecutive days, and that the number of visits required must vary according to the circumstances of each case, the midwife remaining responsible if anything went wrong with the patient owing to the omission of a visit, and that any visit paid by an assistant should not be in substitution for, but in addition to, a visit of the midwife. Letters were considered from the superintendent and the matron of the Government Maternity Hospital, Madras, requesting the Board to hold examinations in Madras. The Board regretted that it was impossible to accede to the application. The Worcestershire county council requested the Board to state the grounds on which it came to the decision to take no further action in the case of a certified midwife against whom the local supervising authority had found a *primâ facie* case of misconduct. Being entirely in sympathy with any endeavour to remove from the Roll the name of a midwife who had been proved to be drunk on duty, the Board regretted as much as the local supervising authority the failure of any such case for want of complete legal proof, but responsibility for the decision in any particular case must remain with the Board alone, and in the case in question the Board, after careful consideration of all the available evidence, came to the conclusion that the charges had not been proved beyond all reasonable doubt. The Devon county council requested the Board to make a rule enabling uncertified women practising as midwives to be granted certificates without examination up to March 31st next. The Board regretted that it could not accede to the request. Dr. J. R. Currie, medical officer of health of Chester, asked the advice of the Board as to taking action against a certified midwife for breaches of the rules. The Board pointed out that it is the duty, under Section 8 (2) of the Midwives Act, 1902, of the local supervising authority and not of the Board to find whether a *primâ facie* case of malpractice, negligence, or misconduct had been established. Sir George Fordham called attention to Clause 7 of the Midwives Bill (No. 2), 1910, and moved a resolution that the Lord President of the Privy Council be asked to receive a deputation from the Central Midwives Board to lay before him the serious objections to this clause of the Bill and the difficulties that must arise if it became law. He contended that the Midwives Roll by this clause would be reduced to an annual list, and that the official machinery for dealing with such annual notification would be very expensive and practically unworkable. Clause 7, relating to proposed annual fee of 1*s*. for keeping a midwife's name on the Roll, is as follows :—

> 7. Every certified midwife shall on or before the thirty-first of January in each year send to the Central Midwives Board on a form to be supplied by the Board for the purpose her name and address, together with a fee of one shilling, and if any certified midwife in any year fails to comply with this requirement her name shall be removed from the roll and thereupon her certificate shall be deemed to be cancelled; but where her name has been so removed on account of such non-compliance she shall at any subsequent time be entitled to have her name restored to the roll and the cancellation of her certificate rescinded on the payment of a fee not exceeding five shillings.

Mr. E. Parker Young moved an amendment to add Clause 11 (1) of the Midwives Bill (No. 2), 1910, to Sir George Fordham's resolution. Mr. Parker Young pointed out that Clause 11 was objectionable because it meant interference with the practice of medical men. Clause 11 (1) of the amending Bill runs as follows :—

> Where a woman certified under the principal Act, who has not given to the local supervising authority such a notice as is mentioned in Section 10 of the principal Act, or a woman not so certified attends any woman in child-birth in any capacity other than that of a midwife, and a duly qualified medical practitioner is not present at the time of the birth, she shall, within forty-eight hours from the birth, give to the local supervising authority notice in writing of the fact that she so attended, and if she omits to do so shall be liable on summary conviction to a fine not exceeding *five pounds*, but nothing in this section shall be construed as exempting any woman practising as a midwife, or holding herself out as so practising, from the obligation to give any notice which, under Section 10 of the principal Act, she is required to give.

The Secretary showed that, to meet the provisions of Clause 7, the staff of the Board would have to be increased and other premises provided, and declared that the clause would seriously cripple the power of the Board. The amendment was lost, and the resolution moved by Sir George Fordham was carried.

PROFESSOR DELEPINE ON BOVINE TUBERCULOSIS.—On Jan. 23rd, at Knutsford, Professor Sheridan Delépine addressed an assembly of farmers on the subject of bovine tuberculosis. He noted the great differences as to the supply of tuberculous milk to Manchester from different districts, varying from 10·5 per cent. of the farms in some districts to 29·7 in others. These farms that produced tuberculous milk were on the whole in a worse condition as to cleanliness than those which did not, but there were striking exceptions, and it was quite clear that cleanliness alone was not a sufficient safeguard. Careful observation tended to show that tuberculous cows "emitting discharges either from the throat or in the form of excreta formed the chief determining factor in the distribution of bovine tuberculosis." Previous to the ulcerative stage the cows were not an active source of danger. But it was necessary that every animal should be inspected and those actively affected removed without delay, and healthy animals should not remain in places which had been used by infected ones. Professor Delépine would reduce as far as possible the number of old animals which were always liable to be the worst affected. The weeding out of tuberculous cows could be done at small cost if it were done while they were under three years old, when they were at their greatest meat value. "At that age, after the slightly affected parts had been removed, the carcass would be perfectly fit for consumption, but at a later age the whole body would probably be condemned at the abattoir, and the loss would be considerable." In the "conquest of consumption" every means must be made use of for preventing the access of tubercle bacilli to the human body, and Professor Delépine is doing good service by endeavouring with such persistent perseverance to close one avenue of

approach. There has been already a great improvement in the milk-supply of Manchester, but the need for watchfulness and care remains as great as ever.

ROYAL SOCIETY OF MEDICINE.—In consequence of the large attendance expected the special general meeting of the Fellows of the Royal Society of Medicine, announced for Tuesday next, Jan. 31st, at 5 P.M., will be held at the Steinway Hall, 15, Lower Seymour-street, London, W.

THE British Institute of Social Service and the Coal Smoke Abatement Society are holding a conference on the "Smoke Evil" at 4, Tavistock-square, London, W.C., on Jan. 30th, at 5 P.M.

DONATIONS AND BEQUESTS.—Under the will of the late Mr. William Henin Christie, the Hastings, St. Leonards, and East Sussex Hospital will receive between £8000 and £10,000.—The Merchant Taylors' Company have voted £1000, payable in annual instalments of £500 each, towards the special fund for the reduction of the capital debt of St. Bartholomew's Hospital.—In connexion with the King's College Hospital Removal Fund, £1000 have been received from Mr. Mortimer Singer for the purpose of naming a bed in the new hospital, and a further £1000 from Mr. F. C. Yates.—Lord Winterstoke has given £5000 towards the cost of the proposed extension of the Bristol General Hospital.

PRESENTATIONS TO MEDICAL MEN.—Mr. T. Gunton Alderton, on his retirement from the post of senior anæsthetist at the West London Hospital after 34 years' service, has been presented by his colleagues on the staff with his portrait, excellently painted by Mr. Edward Mills. The presentation was made by Mr. F. Swinford Edwards at a staff dinner held at the Great Central Hotel, Marylebone. Mr. Alderton is the treasurer and a late president of the West London Medico-Chirurgical Society, a member of the board of management of the West London Hospital, and is professionally associated with several public and philanthropic societies in the Hammersmith district.—A presentation was made at Broughton Astley, Leicestershire, on Jan. 20th, to Mr. E. C. Austin, F.R.C.S. Edin., who is removing from Leicester to Salford. The presentation consisted of an oak bureau and bookcase, and a framed and illuminated address.

THE BROWN DOG.—The case of "the brown dog" was referred to at a meeting of the Battersea borough council on the evening of Jan. 11th. The council was notified that the police precept had been increased by an amount representing ½*d.* in the £. One of the ex-mayors, who took a part in the inauguration of the Brown Dog Memorial, moved that the Commissioners of Police should be asked to reduce the precept by £700. That, he said, was the amount which was stated to have been spent per annum in providing special protection for the brown dog. As the memorial had been removed, of course the £700 were being saved. The motion was seconded by another ex-mayor, who announced that the memorial would have to be restored by the council before very long. Several members pointed out that the cost of special protection was not, as it ought to have been, made a charge on Battersea, but was spread over the whole of London. It would, therefore, be absurd to adopt the proposal. The great majority of the council being of this opinion, the motion was lost.—On the same evening the council decided to adjourn for six months the consideration of the Local Government Board Order authorising metropolitan borough councils to provide a temporary supply of diphtheria antitoxin and temporary medical attendance in connexion therewith for the poorer inhabitants. The subject was much discussed, and the adjournment was opposed for a long time, even by members who are anti-vaccinationists and anti-vivisectionists. Their position was that if there is anything good in antitoxin Battersea ought to have it for Battersea's poor, and ought to have it soon. Mr. S. H. Curry and Mr. J. T. Richards, who are medical practitioners, pointed out that there were dangers connected with the indiscriminate use of antitoxin and that risks attended its injection in dirty rooms. The object of the Local Government Board, Mr. Richards said, was to secure that patients might have the serum earlier than was now the case when they were removed to hospital. Battersea patients, however, could be in hospital within two or three hours after diagnosis. A report on the subject had been prepared by the medical officer of health (Mr. G. Q. Lennane) and had been considered by the health committee. It was decided on Jan. 18th that a copy of the report should be sent to every member of the council.

Dr. Kimmle, general secretary of the Central Committee of the Red Cross in Berlin, has been granted a patent of nobility by the Wurtemburg Government.

A COMMODIOUS children's clinic and sucklings' rearing establishment has been erected at Göttingen at a cost of over £8000 by the parents of Dr. Dreger, who died at an early age, for whose public health he was responsible.

ROYAL METEOROLOGICAL SOCIETY.—The council of the Royal Meteorological Society states that the increased number of applications for lectures on meteorological subjects shows that greater interest is now being taken by the general public in meteorological matters. The researches into the meteorological conditions of the upper atmosphere have been continued under the auspices of the joint committee appointed by the society and the British Association. At the annual meeting held on Jan. 18th, the President, Mr. H. Mellish, said that the completion of the third decade since the society undertook the collection of climatological observations suggested that the moment was opportune for taking stock of the data which had been collected in the British Isles and of the progress which has been made in reducing and discussing them, so he devoted his address to a consideration of the present position of British Climatology. Dr. H. N. Dickson was elected President for the ensuing year.

A NURSING PAGEANT.—The National Council of Trained Nurses of Great Britain and Ireland is planning a pageant, designed by Mrs. Bedford Fenwick, representing the evolution of trained nursing, to be held in the Connaught Rooms, Great Queen-street, London, W.C., on the evening of Saturday, Feb. 18th. The central figure will be Hygeia, goddess of health, supported by the elements, earth, air, fire, and water, and in her train will be the Spirit of Nursing and Science with their attendant attributes. A reception committee has been arranged, including the Lady Helen Munro Ferguson, the Lady Hermione Blackwood, the Dowager Lady Loch, Lady Mackinnon, Lady Beachcroft, Lady Wynne, Mrs. Bedford Fenwick, Mrs. Alec Tweedie, Mrs. Mackenzie Davidson, Mrs. Timbrell Bulstrode, Mrs. Walter Spencer, and a large number of hospital matrons and others interested in the organisation of the nursing profession. Hygeia, the goddess of health, will be impersonated by Miss Irene Fergusson, the Spirit of Nursing will be represented by Miss Audrey Campbell, and Science by Miss Winifred Bridger. Miss M. Mollett has written the masque. All information respecting the pageant, and tickets (reserved seats, 10*s.* 6*d.* and 7*s.* 6*d.*; unreserved seats, 5*s.*; and nurses' tickets, 3*s.* 6*d.*) can be obtained from the pageant secretary, 431, Oxford-street, London, W.

INVALID CHILDREN'S AID ASSOCIATION, BRIGHTON.—To the many agencies that are at work in Brighton and the sister town of Hove on behalf of the poor children another has now to be added—viz., the Invalid Children's Aid Association, which has just completed the first year of its existence. Its objects are to visit and care for the crippled, invalid, and delicate children of the poor; to provide medical advice with special treatment and food if necessary, surgical apparatus, chairs, &c., admissions to hospitals, convalescent homes, and country cottages; and to seek to ameliorate the conditions and brighten the lives of sick and suffering children in the two towns. During the year 110 children were visited and their names will remain on the books until the visitors are satisfied that all has been done that is possible; and thanks to the medical officer of health of Brighton, Dr. Duncan Forbes, several cases which came under the notice of the association were admitted to the sanatorium for treatment of tuberculosis in the bones and joints. The association expects the parents to pay their share in the expenses according to the means at their disposal. The movement is receiving considerable support, and in the first 12 months of its existence has done a beneficent work. Bearing in mind the many kindred organisations that are at work in Brighton and Hove, it certainly cannot be said of these towns that they are behindhand in their endeavours to improve the race.

# Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

DAVIES, T. B., M.B., B.S. Lond., has been appointed House Surgeon at University College Hospital.

HAVELOCK, SYDNEY, M.B., B.S. Durh., D.P.H., has been appointed Second Assistant Medical Officer to the Newcastle Education Committee.

HERRING, J. F., L.R.C.P. & S. Edin., has been appointed Medical Officer and Public Vaccinator to the Atherstone Union and Medical Officer of Health for the Atherstone Rural District Council.

HIGGS, FREDERICK W., M.B. Lond., M.R.C.P. Lond., has been appointed Physician to In-Patients at the Belgrave Hospital for Children.

MCCULLY, D., M.R.C.S., L.R.C.P. Lond., has been appointed Obstetric Assistant at University College Hospital.

MACILWAINE, J. E., M.D., Ch.B. R.U.I., D.P.H., has been appointed House Physician to the Royal Victoria Hospital, Belfast.

MCKAY, ROBERT, L.R.C.P. Lond., M.R.C.S., L.D.S., has been appointed Dental Surgeon to St. Thomas's Hospital.

MORRIS, C. W., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician at University College Hospital.

NICOLL, AGNES M., M.B., Ch.B. St. And., D.P.H. Manch., has been appointed Junior Resident Medical Assistant at the Dundee East Poorhouse and Hospital.

PARKER, R. P., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Superintendent Medical Officer of Oldham Workhouse.

PRICE, L. E., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Nuneaton District of the county of Warwick.

STRAIN, THOMAS, M.D. Glasg., D.P.H. Camb., has been appointed Medical Officer of Health and Medical Superintendent of the Isolation Hospital of the Urban District of Barnes.

WALKER, W., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Mid-Calder District of the county of Edinburgh.

# Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

ABERDEEN POORHOUSE.—Senior Resident. Salary £200 per annum, with board.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—House Surgeon for six months. Salary at rate of £60 per annum, with board, residence, &c.

BIRKENHEAD UNION INFIRMARY AND SANATORIUM.—Senior Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments.

BIRMINGHAM CITY HOSPITAL, Lodge-road.—Assistant Medical Officer. Salary £120 per annum, with board, residence, &c.

BOURNEMOUTH, ROYAL BOSCOMBE AND WEST HANTS HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, lodging, and washing.

BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £100 per annum.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—Assistant House Surgeon, unmarried. Salary £60 per annum, with apartments, board, and laundry.

BRISTOL ROYAL INFIRMARY.—Two House Physicians and One House Surgeon. Salary £100 each per annum. Also One Obstetric and Ophthalmic House Surgeon, and One Throat, Nose, and Ear House Surgeon. Salary £75 each per annum. Also Casualty Officer for six months. Salary £50 per annum. Apartments, board, and laundry are provided.

CAPETOWN, SOMERSET HOSPITAL.—Two Assistant Medical Officers. Salary £200 per annum, with rations and quarters.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—House Surgeon. Salary at rate of £50 per annum, with board and residence.

CHESHIRE EDUCATION COMMITTEE.—Third Assistant Medical Inspector of School Children. Salary £350 per annum.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £75 per annum, with board, washing, and residence.

DAVOS, QUEEN ALEXANDRA SANATORIUM.—Junior Pathologist and Bacteriologist.

DELAMERE FOREST, CHESHIRE, CROSSLEY SANATORIUM.—Assistant Medical Officer. Salary £100 per annum, with board, apartments, and laundry.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £75 per annum, with residence, board, and washing.

DUNBARTON COUNTY SECONDARY EDUCATION COMMITTEE.—Two Medical Inspectors of School Children. Salary £300 per annum.

ECCLESALL BIERLOW UNION WORKHOUSE.—Resident Assistant Medical Officer. Salary £150 per annum, with board, washing, and apartments.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, London, S.E.—House Surgeon for five months. Salary at rate of £60 per annum, with board, residence, and washing.

GRAVESEND HOSPITAL, KENT.—House Surgeon. Salary £100 per annum, with board and residence.

HARRIS PARISH COUNCIL.—Medical Officer and Public Vaccinator. Salary £110 per annum.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—Honorary Dental Surgeon.

LEITH HOSPITAL.—Medical Registrar.

LINCOLN COUNTY HOSPITAL.—Senior House Surgeon, unmarried. Salary £125 per annum, with board, lodging, and washing.

LIVERPOOL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Mount Pleasant.—Assistant Medical Officer and Pathologist. Salary £200 per annum.

LIVERPOOL INFECTIOUS DISEASES HOSPITAL.—Assistant Resident Medical Officer, unmarried. Salary £120 per annum, with board, lodging, and washing.

LONDON TEMPERANCE HOSPITAL.—Assistant Resident Medical Officer for six months. Salary at rate of 50 guineas per annum, with board, residence, and washing.

MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Assistant House Surgeon, unmarried. Salary £80, with board and residence.

MANCHESTER, CHORLTON-ON MEDLOCK DISPENSARY.—Resident House Surgeon, unmarried. Salary £120 per annum, with rooms and attendance.

MIDDLESBROUGH, NORTH RIDING INFIRMARY.—House Surgeon. Salary £100 per annum, with residence, board, and washing.

NATIONAL DENTAL HOSPITAL AND COLLEGE, Great Portland-street, W.—Anæsthetist.

OXFORD, RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—House Physician and Junior House Surgeon, both unmarried and for six months. Salary in each case at rate of £80 per annum, with board, &c.

PARK HOSPITAL FOR CHILDREN, Hither Green, S.E.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Assistant Surgeon.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Pathologist. Salary £50 per annum. Also Honorary Anæsthetist once a week. Salary £20 per annum.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Resident Medical Officer for four months. Salary at rate of £60 per annum, with board, residence, and washing.

RAINHILL COUNTY ASYLUM, near Liverpool.—Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, attendance, and washing.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Medical Officer in Charge of Department for X Rays and Electro-therapy. Salary at rate of £60 per annum.

ROYAL NAVAL MEDICAL SERVICE.—Twelve Commissions.

SALISBURY INFIRMARY.—Assistant House Surgeon, unmarried. Salary £50 per annum, with apartments, board, lodging, and washing.

SHEFFIELD ROYAL INFIRMARY.—Seventh Resident Medical Officer. Salary £60 per annum, with board and residence.

SOUTHAMPTON, FREE EYE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and residence.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Honorary Medical Registrar.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—Resident House Surgeon. Salary £120 per annum, with board and lodging.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL.—House Physician.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Broughton Astley, in the county of Leicester.

# Births, Marriages, and Deaths.

## BIRTHS.

EWENS.—On Jan. 20th, at West Chase, Maldon, Essex, the wife of Henry L. Ewens, M.D., of a son.

GARDINER.—On Jan. 15th, at Dunmow, Essex, the wife of J. Napier Gardiner, M.D., of a daughter.

HOVENDEN.—On Jan. 15th, at Compton Lodge, East Sheen, S.W., the wife of Arthur C. Hovenden, M.B., B.S. Lond., of a son.

MARRIAGE.—On Jan. 23rd, at 109, Harley-street, W., the wife of H. J. Marriage, M.B., B.S. Lond., F.R.C.S. Eng., of a son.

NEWINGTON.—On Jan. 18th, at The Croft, Edenbridge, Kent, the wife of C. W. H. Newington, M.R.C.S., L.R.C.P., of a son.

## MARRIAGES.

IRWIN—SINCLAIR.—On Jan. 17th, 1911, at Fitzroy Church, Belfast, by the Rev. William Colquhoun, B.A., assisted by the Rev. Charles Davey, B.A., Samuel Thompson Irwin, M.B., M.Ch., F.R.C.S., Belfast, son of John Irwin, Bovally, Limavady, to Mary Jemima (May), only daughter of the late A. W. Sinclair, J.P., Newry, and Mrs. Sinclair, 1, Wellington Park-terrace.

## DEATHS.

MELLAND.—On Jan. 17th, at Victoria Park, Rusholme, Manchester, Frederick Melland, M.R.C.S., L.S.A., in his 93rd year.

POWER.—On Jan. 18th, at Bagdale Hall, Whitby, Yorkshire, Henry Power, M.B. Lond., F.R.C.S. Eng., in his 81st year.

TYRRELL.—On Jan. 20th, at "Claremont," Malvern, Walter Tyrrell, M.R.C.S., L.S.A., aged 79 years.

VEASEY.—On Jan. 17th, at Aspley Guise, Beds, Henry Veasey, F.R.C.S., aged 92 years.

VULLIAMY.—On Jan. 23rd, after a short illness, Justin Theodore Vulliamy, M.R.C.S., aged 42 years.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## A DIABETES CURE.

A CORRESPONDENT recently submitted to us a diabetes cure with the request to have it examined. He was called to see a patient who had been taking it. She was unstable on her legs, excited, and had dilated pupils—symptoms which she attributed to the nostrum. It evidently consisted of the dried leaves of some herb. Submitted to analysis in THE LANCET Laboratory no alkaloid could be found, but there was a decided amount of tannin present and an aromatic oil. The curator of the Museum of the Pharmaceutical Society of Great Britain, Mr. E. M. Holmes, F.L.S., F.E.S., kindly examined the "remedy." He expressed the opinion that it was Polygonum hydropiper, L., commonly known as water pepper. The fruits of Polygonum were, he states present, and although the few perfect leaves evident would do either for the spiral leaves of P. hydropiper or for the ordinary leaves of P. aviculare, the herb had the biting taste characteristic of water pepper. P. hydropiper is used for dropsy and P. aviculare for difficulty of passing urine, so that both would appear to have some action on the kidneys. According to W. T. Fernie, M.D. ("Herbal Simples"), the water pepper, or arsmart, grows abundantly by the sides of lakes and ditches in Great Britain. It bears a vulgar English name signifying the irritation which it causes when applied to the fundament; and its French sobriquet, *culrage*, conveys the same meaning:—

"An erbe is the cause of all this rage
In our tongue called culrage."

"Fleas will not come into rooms where this herb is kept. It is used for curing proud flesh in the sores of animals, and the leaves serve the purpose of a mustard poultice. A piece of the plant may be chewed to relieve toothache, as well as to cure small ulcers of thrush in the mouth. It has been used in jaundice and cholera. Another polygonum, the great bistort, is strongly astringent, and has been used for a spongy state of the gums." The packet containing the remedy bore the inscription "Van Veen and Co., Import van China and Japan, Amsterdam," and also an inscription written in Chinese characters.

## DEVONSHIRE SUPERSTITIONS.

THE *Bristol Times and Mirror* states that in some parts of Devonshire a mother believes that if she imprisons a live spider in a nutshell and ties it round her infant's neck when the child is suffering from whooping-cough, that the disease will disappear when the spider dies. This newspaper remarks that a little girl went to a Tiverton shopkeeper and said to him, "Will you please give mother a nut to put a spider in, as baby's got the whooping-cough."

## THE EASY SALE OF PISTOLS.

THE ease with which the sale of pistols may be conducted without compliance with the provisions of the Act of Parliament which is supposed to regulate such transactions was exemplified recently in a prosecution at the Guildhall police court. The police at Canterbury found there a man in possession of a revolver and cartridges without a licence or permit to carry firearms. He was a perfectly respectable man, and he gave the police full information as to how and where he purchased the revolver in London, with the result that proceedings were taken against Ernest Reeves, an assistant in the Anglo-Saxon Motor and Cycle Company, of Newgate-street. It was proved that the purchase was made without any of the prescribed formalities being observed at a branch establishment of the firm named, the defendant alleging that the customer came to see the goods, which had been obtained expressly for him from the head office, on Christmas Eve, just before closing-time; that he said he would take them with him, and that in the pressure of business he was allowed to do so, instead of being referred to the Newgate-street establishment as intended by the defendant. An awkward circumstance for the defendant to explain was the fact that the bill given to the purchaser contained no mention of a revolver, the sum paid being described as for repairing a gun. This he sought to explain as a slip due to copying a similar entry of "repair gun" made already on the same day in the day-book. A fine of £5 was inflicted with the alternative of a month's imprisonment, the Alderman expressing regret that he could not make the punishment four times as heavy.

## APT HOSPITALITY.

THE annual dinner to the coachmen and chauffeurs in the employ of medical men in Leicester took place at the De Montfort Hotel, Leicester, on Saturday, Jan. 21st. A hearty vote of thanks was passed to the medical men of the town for providing the necessary funds.

THE Council of the Chelsea Hospital for Women states, for the information of any that may receive unauthorised appeals, that it has discontinued the use of collecting boxes outside the hospital precincts.

*E. C. A.* will find the answer to his question not very clearly given in the Medical Acts. The representation by an unqualified person that he is a duly registered practitioner is punishable.

ERRATUM.—In our issue of Jan. 21st, p. 148, by a printer's error, Mr. R. F. Mann was referred to as photographer and assistant in the electrical department of the Willesden Hospital, instead of the *Middlesex* Hospital.

**COMMUNICATIONS not noticed in our present issue will receive attention in our next.**

## A DIARY OF CONGRESSES.

**THE following Congresses, Conferences, and Exhibitions are announced for 1911:—**

**Feb. 20th–25th (Cairo).—Fifth International Congress for the Blind.**
**March 2nd–6th (Berlin).—Thirty-second Balneological Congress.**
**,, 23rd (Paris).—First Congress of French Medical Journalists.**
**April (Berlin).—German Surgical Congress. (Thirty-ninth Annual Meeting.)**
**April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.**
**April 18th–20th (Paris).—Third Congress of Physiotherapy of French-speaking Physicians.**
**,, 19th–22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.**
**,, 20th–22nd (Groningen).—Thirteenth Nature and Medical Congress.**
**May 30th (The Hague).—International Congress on Opium.**
**May (Washington).—Conference on the Protection of Industrial Property. (Question of False Marking of Goods.)**
**May–October (Dresden).—International Hygiene Exhibition.**
**May–October (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)**
**May–October (?) (London, Shepherd's Bush).—Coronation Exhibition.**
**June (Paris).—First Congress of the International Medical Association for the Prevention of War.**
**,, (Los Angeles, Cal.).—American Medical Association.**
**June 5th–8th (Kolberg, Prussia).—Fifth International Congress of Thalassotherapy.**
**June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.**
**July (Birmingham).—British Medical Association.**
**July 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.**
**August 15th–21st (Dublin).—Royal Institute of Public Health.**
**,, 30th–Sept. 6th (Portsmouth).—British Association.**
**August or September (Berlin).—Third International Laryngo-Rhinological Congress.**
**September (Brussels).—Exhibition of Fractures.**
**,, (Turin).—International Congress of Pathology.**
**,, (Genoa).—International Exhibition of Marine Hygiene.**
**September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.**
**Sept. 11th–15th (Berlin).—National Congress for the Study and Prevention of Infantile Mortality (*Goutles de Lait*).**
**,, 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.**
**,, 18th–23rd (Sydney).—Australasian Medical Congress.**
**,, 18th–24th (Turin).—Fourth National Congress of Hygiene.**
**,, 24th–30th (Rome).—International Congress on Tuberculosis.**
**,, 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.**
**October (Cologne).—International Congress of Criminal Anthropology.**
**Oct. 1st–4th (Liége).—Second Congress of Alimentation.**
**Dec. 4th–9th (Havana, Cuba).—American Public Health Association.**
**(Date not fixed) (Montreal).—Canadian Medical Association.**
**(Date not fixed) (Rome).—International Exhibition of Social Hygiene.**
**(Date uncertain) (Turin).—International Exhibition of Industry and Labour.**

**In 1912:—**
**Spring (London).—Second Optical Convention.**
**July (?) (Cologne).—International Congress of Nurses.**
**September (Prague).—International Congress of Radiology and Medical Electrology.**
**September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.**
**,, Visit of German Medical Men to America.**
**Nov. 22nd–29th (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.**

**In 1913:—**
**(London).—Seventeenth International Congress of Medicine.**
**(London).—Historical Medical Exhibition. (Organised by Mr. Henry S. Wellcome.)**
**(Dresden (?)).—International Conference on Cancer.**
**(Washington).—Congress of American Physicians and Surgeons.**
**August (Buffalo).—Fourth International Congress of School Hygiene.**

**In 1914:—**
**(Vienna).—Third International Congress for Professional Diseases.**

**In 1915:—**
**(London).—International Prison Congress.**
**(London).—Imperial Exhibition (?)**

# Medical Diary for the ensuing Week.

## SOCIETIES.

**ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).**

TUESDAY.

A SPECIAL GENERAL MEETING OF FELLOWS OF THE SOCIETY will be held at Steinway Hall, Lower Seymour-street, W.: at 5 P.M.

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—G. F. Blacker, J. H. Targett), at 11, Chandos street, W.: at 8 P.M.

*Discussion:*

On the Indications for, and Technique of, Cæsarean Section, and its Alternatives in Women with Contracted Pelves, who have been Long in Labour and Exposed to Septic Infection (opened by Dr. Amand Routh). The following gentlemen will take part:—Dr. Hastings Tweedy, Dr. Briggs, Dr. Edge, Dr. Fitzgerald, Dr. Arnold Lea, Dr. H. Spencer, Dr. Rayner, Dr. Lewers, Dr. Ernest Shaw, and Dr. Gow.

The Discussion will be continued on the following day.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—L. Hemington Pegler, W. H. Kelson), at 11, Chandos-street, W.: at 5 P.M.

*Cases and Specimens:*

By Dr. William Hill, Mr. F. Rose, Dr. L. H. Pegler, Mr. H. Tilley and others.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION, at 11, Chandos-street, W.: at 8 P.M.

*Discussion* (continued from Thursday):

The following gentlemen will take part:—Dr. Maxwell, Dr. Munro Kerr, Dr. Herman, Dr. Lloyd Roberts, Mrs. Scharlieb, Dr. A. W. Wallace, Dr. A. W. Russell, Dr. H. Roberts, Dr. Eden, Dr. S. Cameron, and the President (Dr. Macnaughton-Jones).

SECTION OF ANÆSTHETICS (Hon. Secretaries—R. W. Collum, Mrs. Dickinson Berry): at 8.30 P.M.

Dr. McCardie: Death during Anæsthesia.
Mr. Gill: Anæsthesia in Post-pharyngeal Abscess.
Dr. Blumfeld: Reflex Effects from Stimulation of the Nasal Mucous Membrane during Anæsthesia.
Dr. Hughes: Cheyne-Stokes Respiration during Anæsthesia.
Mr. Coleman: A New Form of Stop-cock for Gas and Air Administration.

**NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.**

THURSDAY.—4.15 P.M., Clinical Cases.

**WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital.**

FRIDAY.—8 P.M., Pathological Exhibits will be shown.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.**

WEDNESDAY.—5 P.M., Prof. F. W. Edridge-Green: Colour Vision and Colour Blindness—The Theory and Facts of Colour Vision and Colour Blindness (Hunterian Lecture).

FRIDAY.—5 P.M., Prof. F. W. Edridge-Green: Colour Vision and Colour Blindness—The Detection of Colour Blindness from a Practical Point of View (Hunterian Lecture).

**UNIVERSITY OF LONDON** (ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.).

THURSDAY.—5 P.M., Mr. R. H. Burne: Comparative Anatomy of the Internal Ear.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.**

MONDAY.—4 P.M., Dr. J. G. Little: Clinique (Skin). 5.15 P.M., Lecture:—Dr. P. Kidd: Some Affections of the Mediastinum.
TUESDAY.—4 P.M., Dr. J. Taylor: Clinique (Medical). 5.15 P.M., Lecture:—Dr. W. H. Stoddart: On Nervous Exhaustion.
WEDNESDAY.—4 P.M., Mr. C. A. R. Nitch: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. L. Mummery: Piles, their Pathology and Treatment.
THURSDAY.—4 P.M., Mr. E. L. Evans: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. J. E. Squire: Bronchitis.
FRIDAY.—4 P.M., Mr. H. Tilley: Clinique (Ear, Nose, and Throat).

**POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.**

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine (Lecture III.).

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. R. Jones: Preventible Insanities.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Mr. Ll. Williams: Extraction of Teeth, When and How to Extract.

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery (Lecture III.)

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Bernstein: Clinical Pathology.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

**LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.**

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4.30 P.M., Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.**

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. E. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).
TUESDAY.—Clinic:—10 A.M., Medical Out-patient (Dr. A. G. Auld). Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 2.30 P.M., Operations. 3.30 P.M., Medical In-patient: (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Mr. F. Trewby: Obstruction to Free Respiration and its Influence on Anæsthesia.
WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).
FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.**

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Batten: Polioencephalo-myelitis.
FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. Ormerod.

**HOSPITAL FOR SICK CHILDREN** (UNIVERSITY OF LONDON), **Great Ormond-street, W.C.**

TUESDAY.—5.15 P.M., Demonstration:—Mr. H. A. T. Fairbank: Deformities—Torticollis; Congenital Affections of the Upper Extremity; Obstetric Paralysis. (Special Post-Graduate Course.)
THURSDAY.—4 P.M., Demonstration—: Dr. Colman: Medical Cases.
FRIDAY.—5.15 P.M., Demonstration:—Mr. H. A. T. Fairbank: Deformities—Kyphosis; Lordosis; Neurotic Spine; Pigeon-toe (Special Post-Graduate Course.)

**ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.**

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Fungous Diseases of the Hair—I., Hyphogenic Sycosis; II., Tinea.

**ANCOATS HOSPITAL, Manchester.**

THURSDAY.—4.15 P.M., Dr. C. H. Melland: Some Features of Heart Disease. (Post-Graduate Clinic.)

## OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY (30th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

**TUESDAY (31st).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

**WEDNESDAY** (1st).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

**THURSDAY** (2nd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

**FRIDAY** (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor. 9 A.M., Major, 2 P.M.).

**SATURDAY** (4th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

**At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.**

**The following journals, magazines, &c, have been received:**—International Journal of Surgery, Bulletin de l'Académie de Médecine, Public Health Reports of the Marine Hospital Service, U.S.A., Birmingham Medical Review, Annual Medical Report to the Hampshire County Council, Allgemeine Medizinische Central-Zeitung, La Semana Médica, Revue de Chirurgie, Revue de Médecine, Asylum News, Review of Neurology and Psychiatry, Transactions of the Society of Tropical Medicine and Hygiene, British Journal of Dental Science, The Journal of Laryngology, Journal of Anatomy and Physiology, The Eugenics Review, London Hospital Gazette, Centralblatt für Allgemeine Pathologie und Anatomie, Allgemeine Wiener Medizinische Zeitung, American Journal of Surgery, Gazette des Hôpitaux, Electrical Engineer, Journal of Tropical Medicine and Hygiene, Symon's Meteorological Magazine, Dublin Journal of Medical Science, American Journal of Obstetrics, The St. Paul Medical Journal, Indian Medical Record, Gazzette Degli Ospedali, Uric Acid Monthly, Indian Public Health, The Quarterly Bulletin of Northwestern University School, Chicago, New York Medical Journal, Revue Clinique d'Andrologie et de Gynécologie, Electrical Review, Science Progress.

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1910 were given in THE LANCET of Dec. 31st, 1910.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1910 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 1 0 | One Year ... ... ... | £1 5 0 |
| Six Months ... ... ... | 0 12 6 | Six Months ... ... ... | 0 14 0 |
| Three Months ... ... | 0 6 6 | Three Months ... ... | 0 7 0 |

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

### TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

## METEOROLOGICAL READINGS.

# The Hunterian Lectures

ON

# COLOUR VISION AND COLOUR BLINDNESS.

*Delivered before the Royal College of Surgeons of England on Feb. 1st and 3rd, 1911,*

BY F. W. EDRIDGE-GREEN, M.D. DURH., F.R.C.S. ENG.,

BEIT MEDICAL RESEARCH FELLOW.

## LECTURE I.

*Delivered on Feb. 1st.*

GENTLEMEN,—Colour blindness is not a good name for the condition to which it is applied, and still worse is the use of the term red blindness or green blindness. In the majority of cases of colour blindness there is no blindness to colours in the ordinary acceptation of the term; a green, red, or yellow light produces a very definite sensation of colour. Those who confuse red and green do so, not because they see red as green or green as red, but because both give rise to a similar sensation of colour. The word light must be used in the sense of referring to those waves which excite the organ of vision. Because two stimuli excite a sensation of light it does not follow that they are similar. We cannot, for instance, distinguish by the eye polarised light from non-polarised light. We have to distinguish between the physical stimuli by their physical properties apart from their effect on the organ of vision. I propose to divide the subject into two parts and in this lecture to deal with the theory and facts of colour-vision and colour blindness, and in the second lecture with the detection of colour blindness from a practical point of view.

### I.—THE THEORY AND FACTS OF COLOUR VISION AND COLOUR BLINDNESS.

The following is the theory which I have propounded in order to explain vision and colour vision. A ray of light impinging on the retina liberates the visual purple from the rods and a photograph is formed. The rods are concerned only with the formation and distribution of the visual purple, not with the conveyance of light impulses to the brain. The ends of the cones are stimulated through the photo-chemical decomposition of the visual purple by light (very probably through the electricity which is produced), and a visual impulse is set up which is conveyed through the optic nerve fibres to the brain. The character of the stimulus differs according to the wave-length of the light causing it. In the impulse itself we have the physiological basis of the sensation of light, and in the quality of the impulse the physiological basis of the sensation of colour. The impulse being conveyed along the optic nerve to the brain stimulates the visual centre, causing a sensation of light, and then passing on to the colour-perceiving centre causes a sensation of colour. But though the impulses vary in character according to the wave-length of the light causing them, the retino-cerebral apparatus is not able to discriminate between the character of adjacent stimuli, not being sufficiently developed for the purpose. At most seven distinct colours are seen, whilst others see in proportion to the development of their colour-perceiving centres only six, five, four, three, or two. This causes colour-blindness, the person seeing only two or three colours instead of the normal six, putting colours together as alike which are seen by the normal sighted to be different. In the degree of colour blindness just preceding total only the colours at the extremes of the spectrum are recognised as different, the remainder of the spectrum appearing grey. Though my own opinion is that the ordinary form of congenital colour-blindness is caused by a defective development of the portion of the brain whose function is the perception of colour we must not exclude any portion of the retino-cerebral apparatus, defect of which would have exactly the same result. It will be noticed that the theory really consists of two parts, one concerned with the retina and the other with the whole retino-cerebral apparatus. I shall in these lectures use the word cerebral in this sense. I am not aware of a single fact which does not support this theory, and I have used it to predict facts which have subsequently been rediscovered by others and now form a part of our common knowledge.

THE VISUAL PURPLE THE ESSENTIAL FACTOR IN VISION.

I will now state very briefly the evidence which supports the view that the visual purple is the essential factor in the retina which enables it to transform light into visual impulses.

1. *Anatomical.*—In the fovea of the retina only cones are to be found. Immediately external to this each cone is surrounded by a ring of rods. The number of rings of rods round each cone increases as the periphery is reached. The outer segments of the cones are situated in a space which is filled with fluid. The external limiting membrane retains this fluid in its place. I find [1] four depressions or canals which lead into the larger depression of the external fovea. These canals appear to have smaller branches and serve to conduct the visual purple into the part of most acute vision. The cones which are present in the fovea have very long outer segments which would present a greater surface for photo-chemical stimulation. The visual purple is only to be found in the rods and not in the cones. I determined to ascertain whether the visual purple could be seen between the cones in the fovea. I have examined under the microscope the retinas of two monkeys which had been kept previously in a dark room for 48 hours. The yellow spot was the reddest part of the whole retina, and the visual purple was seen to be between and not in the cones.[2]

2. *Physiological analogy with other body cells.*—It is far more probable that the rods should produce a secretion which would affect other cells rather than themselves. The liver cells do not form bile in order to stimulate themselves, and the internal secretions are produced to affect other parts of the body. I am not aware of a single instance in which a cell produces a secretion which has the function of stimulating the cell producing it. The visual purple is regenerated in the rods by the pigment cells in connexion with them.

3. *The relation between the foveal and the extra-foveal regions.*—As the fovea only contains cones, if any of the older theories of the relative functions of the rods and cones were true, we should expect to find qualitative differences between the foveal and extra-foveal regions. This is not the case, but, as we should expect, if the visual purple were the visual substance all the phenomena which have been attributed to the visual purple should be found in the fovea. Von Tschermak, Hering, Hess, Garten, and others have found the Purkinje phenomenon, the variation in optical white equations by a state of light and dark adaptation, the colourless interval for spectral lights of increasing intensity, and the varying phases of the after-image in the fovea only gradually diminished.

4. *The varying sensibility of the fovea.*—The fovea is in some conditions the most sensitive part of the whole retina and with other conditions the least. Helmholtz has recorded some of these facts and regarded them as quite inexplicable. We have, however, an easy explanation of the facts on the assumption that when there is visual purple in the fovea this is the most sensitive part of the whole retina, but when there is none there time must elapse before it can diffuse into the spot and in the meantime it is insensitive to light. I have devised several experiments which show the visual purple flowing into the foveal region. The following simple experiment shows this very well. If on awaking in the morning the eyes be directed to a dull white surface, as, for instance, the ceiling, the region of the yellow spot will appear as an irregular black spot and light will appear to invade this spot from without inwards. If the eyes be now closed and covered with the hands purple circles will form round the centre of the field of vision and gradually contracting reach the centre. When the circle reaches the centre it breaks up into a star-shaped figure and becomes much brighter. It then disappears and is followed by another contracting circle. Now it will be noticed that if one eye be opened when the circle has broken up, a brilliant rose-coloured star much brighter than any other part will be seen in the centre of the field of

[1] Journal of Physiology, vol. xli., p. 274.
[2] Transactions of the Ophthalmological Society, 1902, p. 300.

vision. This has the exact hue of the visual purple. If we wait until the star has disappeared before opening an eye the macular region appears as a black spot as before. This conclusively shows that the central portion of the retina is sensitised from the peripheral portions.

5. *Chemical analogy.*—The visual purple gives a curve which is very similar to that of many other photo-chemical substances. We know that with photo-chemical substances the chemical effect is not proportional to the intensity of the light. That is, a different curve is obtained with weak light from that which is formed with light of greater intensity. It is reasonable, therefore, to suppose that the visual purple which is formed by the pigment cells under the influence of a bright light would be somewhat different in character from that which is formed in darkness. Again, from the chemical analogy which I have just given, even if the visual purple were of the same character, we should not expect similar curves with different intensities of light. It is probable that both factors are in operation. This deduction gives an explanation of the Purkinje phenomenon, or the fact that when the eyes are adapted to darkness the point of greatest luminosity is shifted more towards the violet end of the spectrum. Some dichromics who have shortening of the red end of the spectrum have a luminosity curve which is very similar to that of a normal-sighted person with a spectrum of lesser intensity. We have only to assume in these cases either that the receiving nervous apparatus is less responsive or that the visual purple formed at one intensity of light is similar to that formed at a lower intensity by a normal-sighted person. We also have an explanation of other conditions, such as erythropsia or red vision, white objects appearing more or less red. If we suppose that the eye has remained in a state of light adaptation, the visual purple produced being more sensitive to the red rays, objects appear of this colour. As we should expect, erythropsia is frequently associated with hemeralopia, or difficulty in seeing in the twilight, the eyes being adapted to light and not to darkness. In green vision the eyes have probably remained in a condition of more or less adaptation to darkness, and are therefore more sensitive to the green rays.

6. *Disappearance of lights falling upon fovea.*—If the cones are not sensitive to light a ray of light falling upon the fovea alone and not upon the adjacent portion of the retina containing rods should produce no sensation of light, provided that there is not already any visual purple in the fovea. It has been known to astronomers for a long time that if a small star in a dark portion of the sky be steadfastly looked at it will disappear from view, whilst other stars seen by indirect vision remain conspicuously visible. The following simple experiment shows the same thing. If a piece of black velvet about three feet square on a door have a pin put in the centre, and the source of light be behind the observer, the pin will be brightly illuminated; and on looking at it (the observer not being too close) and keeping the eye quite still the pin will disappear, the visual substance diffused into the fovea centralis being used up and not renewed. When viewed by indirect vision it is impossible to make it disappear in this way. When I have taken great care to have very dark surroundings and have used only one eye I have made moderately bright lights disappear in this manner. These facts have been attributed to a defective sensibility of the fovea for feeble light. The important point, however, that the light is at first most clearly seen by the fovea and only subsequently fades has been overlooked. If these facts were due to a defective sensibility of the fovea the star or light would not be visible at first.

7. *Illusion of moving light.*—If a small light be looked at fixedly in a dark room it will appear to move until it comes apparently so close that it could be grasped. The reason of this is that the eye moves so that the light falls upon a more peripheral part of the retina. I find that the movement takes place as if some photo-chemical substance acted under the influence of gravity. For instance, when standing the light appears to travel upwards; resting the head on one side it appears to travel in the opposite direction. The light appears as if we were looking straight at it and the eye which is covered up remains directed straight at the object. When the second eye is opened two images of the light are seen and the image which is seen with the periphery of the first eye rapidly coalesces with that seen directly by the second eye.

8. *Purple after-image.*—A positive after-image of a purple (rose) colour can be obtained after white light or any spectral colour. It will be noticed that when there is little light during the subsequent observation the colour of an after-image inclines to blue or green, when there is more light towards purple or red.

9. *Currents seen in the field of vision not due to the circulation.*—It occurred to me that if there were canals in the retina which promoted the easy flow of the visual purple into the fovea we ought to obtain evidence of the currents flowing along these channels entoptically. I found that this was the case and that the currents could be seen in numerous ways.[3] If one eye be partially covered with an opaque disc whilst both eyes are directed forwards in a not too brightly illuminated room and special attention be paid to the covered eye an appearance of whirling currents will be seen with this eye. These currents appear to be directed towards the centre and have a very similar appearance to a whirlpool which is fed by four main branches. These, again, are fed by smaller branches which continually change their paths. On closing both eyes all the portion in which the whirling currents are seen appears as dull purple. These currents cannot be due to vessels, because we know that the centre of the retina corresponding to the point where the greatest movement is seen is free from vessels. The appearance is also very different from that of the movement of blood in vessels. The currents can also be seen in the light, in the dark, through yellow-green glass, and with intermittent light. The main branches form a star-shaped figure with four rays. The currents carry the visual quality, colour, and brightness from whence they come into an after-image. They also tend to move an after-image towards the centre. The currents behave as if they ran in definite channels, but could also overrun, on any further stimulus, the banks of the channels. For instance, a thin bright line with a little more light appears as a broad band and the central star figure will enlarge into a rhomboid, oval, or disc. Movements of the eyes affect the broad currents in the outer part of the field of vision.

10. *Pressure figure.*—Pressure on the front of the eye causes the star-shaped figure to be seen, and this changes into a rhomboid with a little more pressure.

11. *Macular star.*—It occurred to me that we ought to obtain evidence of the canals in the retina in cases where the outflow from the retina is obstructed as by tumour. I find this is the case; the star-shaped figure given by Sir Victor Horsley in his paper on Tumour of the Frontal Lobe[4] is almost exactly the same as that seen subjectively.

12. *Entoptic appearance of cone mosaic.*—Appearances corresponding to the cone mosaic of the retina may be seen in several ways.[5] The appearance seen corresponds to the cone distribution of the retina as viewed from its outer side, the portions occupied by rods appearing as dark spaces.

13. *Visual acuity.*—Visual acuity is most acute with the fovea and diminishes from within outwards. It corresponds very fairly with the cone distribution of the retina. On the other hand, there is not one single fact which points to the rods as being light sentient organs. This is well recognised by those best qualified to judge.[6]

I could give many more facts in support of the view that the visual purple is the visual substance, and I have not yet had brought to my notice any fact which is not readily explicable on that hypothesis. There may be other photo-chemical substances in the retina, but there is not the slightest evidence that such is the case. I regard the visual purple as the sole visual substance. We could, of course, split the visual purple into innumerable simpler photo-chemical substances, each of which has its own absorption curve, having its maximum in some particular part of the spectrum. It is difficult to say at present exactly how the visual purple acts as a stimulus transformer, but this is because so many plausible hypotheses immediately occur to us. It is very probable that light acting upon the visual purple, is, according to its wave-length, absorbed by particular atoms or molecules, the amplitude of their vibrations being increased. These vibrations may cause corresponding vibrations in certain discs of the outer segments of the cones, which seem especially constructed to take up vibrations. We know that when light falls on the

retina it causes an electric current. We know how the telephone is able through electricity to convey waves of sound, and something similar may be present in the eye, the apparatus being especially constructed for vibrations of small wave-length. The current of electricity set up by light may cause the sensation of light and the vibrations of the atoms or molecules the sensation of colour.

In all vital processes there is a condition of katabolism or chemical change in the protoplasm and an anabolic or building-up process, in which the protoplasm is restored to its normal state. We have therefore to consider two definite processes in the visual purple—namely, a breaking down of the visual purple photo-chemically by light and its restoration by the pigment cells and rods. Under ordinary conditions of light and during the whole of the day-time the visual purple is continually being bleached and re-formed. It is obvious, therefore, that when the eye has been kept in the dark and is then exposed to light, an observation taken immediately will not be comparable with one taken a few seconds afterwards, because in the first observation we have only to consider the katabolic change, whilst in the second observation the anabolic change has to be considered as well, as the visual purple has to be reformed for subsequent seeing. There appears to be very little evidence in ordinary circumstances of this anabolic process; for instance, if we fatigue the eye with sodium light in a dark room, and then immediately examine a spectrum, we find that though all the yellow has disappeared there is no increase in the blue—in fact, the blue seems rather diminished than otherwise. Again, there is not the slightest diminution in either the red or green, showing conclusively that yellow cannot be a compound sensation made up by a combination of red and green. We must therefore explain in another way the apparent trichromatism of normal colour vision, which is so well known to every photographer, especially those who are concerned with colour photography. If my theory of the evolution of the colour-sense be the correct one and we have cases of colour-blindness corresponding to every degree of the evolutionary process, we have an explanation of the facts. In past ages all saw the rainbow made up of only three colours—red, green, and violet. When a new colour (yellow) appeared between the red and green, it is obvious that a mixture of red and green would give rise, not to red-green, but to the colour which had replaced it—namely, yellow. The retina, therefore, corresponds to a layer of photo-chemical liquid in which there are innumerable wires each connected with a galvanometer. When light falls upon a portion of this fluid the needle of the galvanometer corresponding to the nearest wire is deflected. The wires correspond to the separate fibres of the optic nerve, and the galvanometers to the visual centres of the brain.

Cases of colour-blindness may be divided into two classes, which are quite separate and distinct from each other, though both may be present in the same person. In the first class there is light as well as colour loss. In the second class the perception of light is the same as the normal sighted, but there is a defect in the perception of colour. In the first class certain rays are either not perceived at all or very imperfectly. Both these classes are represented by analogous conditions in the perception of sounds. The first class of the colour-blind is represented by those who are unable to hear very high or very low notes. The second class of the colour-blind is represented by those who possess what is commonly called a defective musical ear. Colour-blind individuals belonging to this class can be arranged in a series. At one end of this series are the normal sighted, and at the other end the totally colour-blind. The colours appear at the points of greatest difference, and I have classified the colour-blind in accordance with the number of colours which they see in the spectrum. The normal sighted may be designated hexachromic; those who see five colours, pentachromic; those who see four, tetrachromic; those who see three, trichromic; those who see two, dichromic; and those who see none, totally colour-blind. There are many degrees included in the dichromic class. There may, or may not, be a neutral band, and this is widest in those cases approaching most nearly to total colour-blindness. I have recorded a case of a patient who was colour-blind with one eye. It is an interesting fact that for form vision the colour-blind eye was much the better of the two, and he could recognise fine lines in the spectrum with this eye which were not visible to the other. He saw the two ends of the spectrum tinged with colour and the remainder grey. It will be noticed that his colour sensations were limited to the extreme red and the extreme violet—namely, those colours which present the greatest physical contrast to each other. Neither the red nor the violet appeared of the nature of a primary colour, but gave the impression that they were largely diluted with grey. A theory of colour vision must account for a case of this kind and also for the other varieties and degrees of colour-blindness. The trichromic are a very important class, and any theory must account for the fact that they see yellow as red-green, and blue as violet-green. As we should theoretically expect, when there is shortening of the spectrum, the centres of the colours are moved towards the unshortened side.

I will now show on the screen some representations of pictures painted by colour-blind persons. The upper picture is the copy, and the one below is the one which has been painted by the colour-blind artist. He has been given a selection of colours on plates and from them has selected the one which he thought appropriate in each case. It will be noticed that the mistakes made are characteristic of the colour perception of the person painting them. Whenever I show these pictures I am asked why it is that these characteristic mistakes should be made and that the true colour of the object is not used instead. This undoubtedly would be the case if the artist were allowed to match the colours by directly comparing them. But he is not able to do this; he looks at the copy and decides upon the colour of an object and then looks for the colour with which to paint it.

A man rarely uses a hue which he does not see as a definite colour, and therefore it has been quite possible for me to pick out those who are more or less colour-blind in the exhibitors of the picture gallery. For instance, if a trichromic have to paint a yellow object he will decide after looking at it whether it be a red or green in his estimation and represent it accordingly. He will be greatly influenced by the nature of colours in its immediate proximity, because simultaneous contrast is increased in the colour blind. Thus he will certainly represent a yellow which is adjacent to a red as green and a yellow which is adjacent to a green as red.

### THE EVOLUTION OF THE COLOUR SENSE.

There can be no doubt that an evolution of the colour sense has taken place; the only point is how and when did this occur. It is obvious that in those low forms of animal life in which the most rudimentary sense of sight exists there can be no sense of colour. The animal which can only perceive light and shade can only discriminate in a rough way between varying intensities of the stimulus. It is obvious, therefore, that the sense of light must have been developed first and then the sense of colour. The sense of sight must have been first developed for those waves which produce their maximum effect upon the sensitive protoplasm. The next process of development would be for the protoplasm to become sensitive to the waves above and below those which produced the primary stimulus. In the physical stimulus which produces the sensation of light there are two factors to be considered, the length of the wave and its amplitude, the greater the amplitude within certain limits the greater the intensity of the sensation. The wave-length of the physical stimulus is the physical basis of the sensation of colour. How did the sensations of colour first arise? Let us suppose that the physiological effect of the physical stimulus differed according to the wave-length of the physical stimulus.

Let us consider that the eye has reached a stage in which it has become sensitive to a fair range of the spectral rays—that is to say, evolution has proceeded to the extent of making the protoplasm sensitive to rays of light considerably above and below those which first caused a sensation of light. We now have an eye which is sensitive to the greater part of the rays which form the visible spectrum. It is, however, an eye which is devoid of the sense of colour; no matter from what part of the spectrum the rays be taken, the only difference which will be appreciated will be one of intensity. I, however, mentioned that in the physical stimulus there were two variables—wave-length and amplitude of the wave. Let us now suppose that a fresh power of discrimination was added to the eye and that it became able to discriminate between different wave-lengths of light. What would be the most probable commencement of development of the sense of colour? Undoubtedly, to my mind, the differentiation of the physical stimuli which were physically most different.

That is to say, the eye would first discriminate between the rays which are physically most different in the visible spectrum, the red and the violet—that is, presuming the eye had become sensitive to this range. It is probable that it had not, and there has been a steady evolution as to the extent of the spectrum perceived as well as to colour. We have examples of this in those cases of defective light perception in which there is shortening of the red or violet end of the spectrum.

Let us now work out the evolution of the colour sense on the assumption that the rays which are physically most different—namely, red and violet were those which were first differentiated. We know that the various rays differ in their effects on various substances; the red rays are more powerful in their heating effects, whilst the violet rays are more active actinally, as is well known by the readiness with which they act upon a photographic plate, which is scarcely affected by red light. We should now have an individual who would see the spectrum nearly all a uniform grey of different degrees of luminosity, but with a tinge of red at one end and a tinge of violet at the other. There is a great deal of evidence to show that this is how the colour sense was first developed. For instance, in the degree of colour blindness just preceding total the spectrum is seen in this way. I have also examined a woman who became totally colour blind apparently through disease of the ear. I examined her when she had recovered a certain amount of colour sensation; her sensations were confined to the extreme red and violet. As the colour sense developed it was not necessary that the rays should differ so much in refrangibility before a difference was seen, and so the red and violet gradually invaded the grey or neutral band, until at a certain point they met in the centre of the spectrum. Such cases are called dichromics.

The next stage of evolution of the colour sense is when the colour-perceiving centre is sufficiently developed to distinguish three main colours in the spectrum. The third colour, green, appears in the centre of the spectrum—that is, at the third point of the greatest physiological difference. In accordance with the prediction of the theory, I found a considerable number of persons who saw the spectrum in this way, about 1·5 per cent. of men. The trichromic see three main colours in the spectrum—red, green, and violet. They usually describe the spectrum as consisting of red, red-green, green, green-violet, and violet. They do not see yellow and blue as distinct colours and are therefore in continual difficulty over them. There are very few of the tests in general use which can detect them, especially if names be not used. They will usually pass a matching test with ease. An examination with the spectrum shows that their colour perception is less than the normal in every part, though the curve has the same general shape. The three trichromics described in my recent paper[7] on the Relation of Light Perception to Colour Perception each saw ten consecutive monochromatic patches in the spectrum instead of the 18 or 19 seen by those who see six colours in the spectrum. It is easy to show that the trichromic are dangerously colour-blind. They will mark out with my colour-perception spectrometer a patch containing greenish-yellow, yellow, and orange-yellow, and declare that it is absolutely monochromatic. When tested with coloured lights they find great difficulty with yellow and blue. Yellow is continually called red or green.

There are several other degrees of colour perception, and it may be well to say a word or two about them, though I class all above the trichromic with the normal-sighted for practical purposes, as they are not dangerously colour blind and can always in ordinary circumstances distinguish signal lights correctly. In the next stage of evolution four colours are seen in the spectrum, and the fourth colour appears at the fourth point of greatest physiological difference—namely, at the orange-yellow of the hexachromic or six-colour people. These people I have designated "tetrachromic," because they see four distinct colours in the spectrum—that is, red, yellow, green, and violet. They do not see blue as a definite colour and are continually classing blues with greens; they usually prefer to call blue purplish-green. In the next stage in evolution there appeared those who see five colours in the spectrum—red, yellow, green, blue, and violet, blue being now recognised as a definite colour; these are the pentachromic group. These people pass all the tests in general use with ease. They, however, have a definitely diminished colour perception compared with the normal or those who see six colours in the spectrum. They mark out in the spectrum only 15 monochromatic patches instead of 18. They cannot see orange as a definite colour; for instance, they can never tell whether a strontium light, which is red, or a calcium light, which is orange, is being shown them.

In the next stage of evolution orange is recognised as a definite colour, and thus we get the hexachromic or normal group, and, as we should theoretically expect, the yellow of the pentachromic is now split up into two colours—orange and yellow. The last stage of evolution which we appear to have reached are those who see seven colours in the spectrum, and the additional one is called indigo. These constitute the heptachromic group, and this seventh colour appears at the exact point which it should appear, according to my theory—namely, between the blue and violet. Persons belonging to this class have a marvellous colour perception and memory for colours. They will indicate a certain shade of colour in the spectrum, and then next day will be able to put the pointer at precisely the same point, a feat which is quite impossible to the ordinary normal-sighted person. They see a greater number of monochromatic patches in the spectrum than the hexachromic, but the curve has the same form. The marking out of the heptachromic does not appear correct to those who see six colours; for instance, the blue appears to invade the green, and the indigo does not appear a definite colour at all. If, however, we bisect the blue of the seven-colour man, and then bisect his indigo, on joining the centres we get the blue of the six-colour man, showing most definitely that the blue has been split up into two fresh colours. It will be noticed that there is room for much further evolution, and we could go on splitting up the spectrum indefinitely if only we had the power to distinguish these finer differences, but as a matter of fact, I have never met with a normal-eyed man who could see more than 29 monochromatic patches in the spectrum, and there are really millions, though by monochromatic patches I do not mean 29 separate colours. Not only are all the details of the process of the evolution of the colour-sense supported by all the facts that we can obtain from literature and museums, but the theory accounts for facts which were previously inexplicable. The distinction between light sensation and colour sensation is explained, and all facts of colour-mixing, complementary colours, and simultaneous contrast. We can understand how, as in many cases which have been recorded, a man may lose his colour perception and still have an unaltered sense of luminosity and visual acuity.

The explanation of complementary colours is a fundamental part of the theory. It is obvious that the two colours of the dichromic are only recognised as different, because they are seen in contrast to each other and that when they are mixed they neutralise each other. It is the same with the other colour sensations, when they are developed they replace the colours occupying their positions. Therefore, green which replaces the grey of the dichromic should be, and is complementary to the other two colour sensations red and violet combined. In the same way when the yellow sensation replaces the red-green of the trichromic it should be possible to compound it of both. Also, when the green sensation is in a feeble state of development it will not have the value that it has at a subsequent stage, and therefore yellow will be a much redder colour to these persons than the normal, and in a colour match of red and green forming yellow more green will be required.

Simultaneous contrast is also explained. When two colours are contrasted each appears to be a colour higher or lower, as the case may be, in the spectrum scale—that is to say, the close comparison exaggerates the difference. As the colour blind have fewer colours simultaneous contrast should be greater with them, and this I have found to be the case.

There may be some relation between the monochromatic patches and the discs in the outer segments of the cones. These are about 16 in number in the guinea-pig. As in photography, the intensity of light is a very important factor in vision. With colours of moderate intensity the periphery of the retina is found to be colour-blind, but this apparent colour blindness disappears when more intense lights are

[7] Proceedings of the Royal Society, B., vol. lxxxii., 1910, p. 458.

used. A person may have shortening of the spectrum with light of moderate intensity, but when the light is increased be able to recognise the spectrum to its normal limit. The change in steepness of gradation according to the intensity of the light is well known to photographers. The Purkinje effect, a change in maximum sensitiveness of the eye according to the intensity of the light, is, in my opinion, a photochemical effect. I find that the Purkinje effect is found for small portions of the retina if a black object has been situated in the corresponding part of the field of vision. The yellow pigment which is found in the yellow spot probably acts like the yellow screen in photography, which, by absorbing the blue and violet rays of the atmosphere, renders visible that which would otherwise be invisible. This is further borne out by the fact that hunters in India are able to hunt later in the day than usual by using spectacles glazed with golden yellow glass.

### THE FACTS OF COLOUR BLINDNESS.

When we consider the path along which a visual impulse has to pass and that each cell has probably some special function in connexion with that impulse, it is not surprising that we meet with a large number of different defects of colour perception and light perception. Defects of light perception are quite distinct from defects of colour perception.

1. *Defects of light perception.*—The person having the defect is placed in a similar position to a normal-sighted person with those particular rays removed or reduced to the same intensity. Defects of light perception may be caused by absorption or by some defect in the visual purple or cerebro-retinal apparatus. The chief defect of light perception which is found is shortening of the red or the violet end of the spectrum. Let us consider the influence of a shortened spectrum upon colour vision. The first evident fact is that bodies reflecting only light, the rays of which occupy the missing portion of the spectrum, appear black.

Nearly all colours are compound—that is to say, the coloured body reflects other rays than those of the colour seen. Thus a blue-green glass may transmit the green, blue, and violet rays of the spectrum. Let us suppose that we have a substance reflecting the green, blue, and three-quarters of the violet, the colour of the body to a normal person being green. Then if we had another substance which reflected the whole of the violet it would appear blue. But with a person who could not perceive the terminal fourth of the violet the colour would look exactly the same as the green one, and as he could not distinguish between the two he would be in continual difficulty with blues and greens. All coloured objects reflecting rays occupying the missing portion appear darker than they do to the normal sighted, and are always matched with darker colours belonging to a point more internal. Thus a dichromic with a shortened red end of the spectrum matches a red with a darker green.

It will be noticed that a shortened spectrum, especially if one end only be affected, may interfere very little with the general appreciation of shade. If, for instance, we take a case in which the red end of the spectrum is shortened, so that only three-quarters of the red of the normal sighted is seen, then all bodies which equally reflect or transmit these rays can be correctly compared, because a similar portion of light has been removed from each. It is only when one colour reflects or transmits the rays occupying the shortened portion and the other does not that there is any definite interference with the appreciation of shade. Again, if neither colour reflects or transmits rays occupying the shortened portion of the spectrum, there will obviously be no interference with the appreciation of shade.

A very common mistake due to shortening of the red end of the spectrum is the confusion of pink and blue. If a person with considerable shortening of the red end of the spectrum is shown a pink which is made up of a mixture of red and violet, the red consisting of rays occupying the missing portion of the spectrum, only the violet is visible to him, and so the pink appears a violet without a trace of red. This pink is, therefore, matched with a violet or blue very much darker than itself.

Mistakes which are due to shortening of the spectrum may be remedied if we subtract the rays occupying the missing portion from the colour of confusion. For instance, if we take a blue and a pink which have been put together as identical by a person with a shortened red end of the spectrum, and look at them through a glass which is opaque to the red but transparent to the remaining rays of the spectrum, both will appear alike in hue and shade. A person with considerable shortening of the red end of the spectrum will look at a red light (which is so dazzlingly bright to a normal-sighted person as to make his eyes ache after looking at it closely for a few seconds) at a distance of a few inches, and remark that there is nothing visible, and that the whole is absolutely black. It is obvious that the light must consist only of rays occupying the missing portion of the spectrum. The same remarks which I have made for a shortened spectrum apply to cases in which there is defect of light perception through absorption or any other cause. The person having the defect is placed in a similar position to a normal-sighted person with those particular rays removed or reduced to the same intensity.

Another effect of shortening of the spectrum when it is sufficient to interfere with the difference perception which appears to be inherent in the central nervous system is that the colours appear to be moved in the direction of the unshortened portion. For instance, we find the neutral point of the dichromic with shortening of the red end of the spectrum in most cases further towards the violet end of the spectrum in comparison with a case in which the spectrum is of normal length. In the same way a trichromic with a shortened red end of the spectrum has the junction of the red and green nearer the violet end than in a case where there is no shortening.

The point that I specially wish to emphasise is that, though every case in which there is defective light perception can be explained by a defective sensibility to light of certain wave-length, not a single case of the very large number of persons that I have examined can be explained on the older theories—that is, the defect of light perception cannot be explained on the assumption that there is a defect in a light perceiving substance which is sensitive to rays of light from a considerable range of the spectrum. A large number of cases in which there is shortening of the red end of the spectrum escape detection when only the green test is used, as is usual according to Holmgren's instructions.

2. *Defects of colour perception.*—The colour blind have a diminished hue perception and see a less number of colours than the normal. All the symptoms of colour blindness are such as we should expect from want of development of the retino-cerebral apparatus for the perception for colour. This is evident even in the slighter cases which show a diminished colour perception compared with the normal. We find that the colour blind are much more dependent on the luminosity of the colour than the normal sighted; they require a stronger stimulus; they fatigue more easily with colours than the normal sighted; they have a more marked simultaneous contrast; the visual angle subtended by the coloured object requires to be larger, and they have a very bad memory for colours. The diminution of colour perception with a diminished visual angle evidently depends upon several causes. It is very marked when there is diminished light perception for those rays which are imperfectly seen. It is also dependent upon certain retinal conditions, as in scotoma and allied conditions. It will be noticed that there are cases, however, who are able to recognise colours under as small a visual angle as the normal sighted, and I have examined one dichromic (said to be red blind by a physicist) who recognised red easily through the thickest neutral glass of my lantern and who had no difficulty with this colour at a distance.

Apart from any other defect of light or colour perception, every case with which I have met has fallen naturally into one of the classes I have given—that is to say, every person is either heptachromic, hexachromic, pentachromic, tetrachromic, trichromic, dichromic, or totally colour blind. When I first gave this classification of colour blindness the facts that I discovered were so at variance with those generally stated that it was very difficult for those who were not well acquainted with the subject to compare the two sets. The general knowledge of the subject has, however, steadily increased, and the facts which I had so great a difficulty in getting recognised now form part of our common knowledge. It would be well, therefore, to describe the two main varieties of colour blindness which are of chief practical importance and to show the relation which they bear to the

writings of other persons. These two main varieties have dichromic and trichromic vision.

1. *Dichromic vision.*—The cases which come under this head form the class of the ordinary red-green blind. It is under this head that nearly every one of the recorded cases may be classed. Vision, as far as colour is concerned, is dichromic, the neutral point being situated in the green of the normal-sighted at about λ 500. All the colours on the red side tend to be confused with each other, therefore red, orange, yellow, and half of the green are seen as one colour, the remainder of the green, blue, and violet as the other. The luminosity curve in uncomplicated cases is similar to the normal. There may be shortening of the spectrum at either the red or the violet end of a varying degree. All degrees of shortening of the red end of the spectrum may be found.

Dichromics with normal luminosity curves are those which were formerly designated green-blind, but this designation is not in accordance with the facts because there is no defect of light perception in the green, and the so-called diagnostic mistakes, as, for instance, putting a bright green with a dark red, are not made. Cases of so-called red-blind are dichromics with shortening of the red end of the spectrum. I have shown that the defective perception of the red end of the spectrum will not account for the dichromic vision which is found in these cases. We may also meet with shortening of the spectrum with otherwise normal colour perception. We also meet with dichromic cases forming a series from almost total colour blindness to those bordering on the trichromic. Any theory must account for the fact that there are varying degrees of colour blindness in dichromic vision and why there is a large neutral band corresponding to the colours of the centre of the spectrum in some cases, and in others the neutral band is so small that the dichromic cannot mark it out. The two colours seen by the dichromic are red and violet, though where no distinction is seen between yellow and red, and blue and violet the brighter colour will often be selected, that is why so many dichromics say that they see yellow and blue in the spectrum. Those who have had practical experience of colour blindness will know, however, that many dichromics make no mistakes with the red test. The following will give the normal-sighted the best idea of colour blindness, and it is how the dichromic see the spectrum and explains why they are able to distinguish between colours. Let him regard the dichromic as a man who has two colours, red and violet and white. The purest red is at the red end of the spectrum; this becomes less and less saturated as the violet is approached until the neutral or white point is reached, then violet comes into the white, and this increases in saturation to the termination of the violet. The ordinary dichromic, therefore, sees green as a much whiter and less saturated colour than red.

2. *Trichromic vision.*—These persons see three distinct colours in the spectrum—red, green, and violet. They describe the region intermediate between red and green—that is to say, the orange and the yellow as red-green and blue as violet-green. It will be seen, therefore, that their chief difficulty is distinguishing yellows and blues. A yellow, for instance, which is situated next to a green will be called red, and the same yellow when adjacent to a red will be called green. There are various degrees of trichromic vision varying from those who are little better than dichromic to those who are tetrachromic. The trichromic rarely find any difficulty with their three main colours—red, green, and violet.

These cases have been described under the name of anomalous trichromatics. This name is one which has been given to those persons who in making a match between a yellow corresponding to the sodium flame and a mixture of thallium green and lithium red make a mixture which is different from that of the normal. A man who puts too much green in the mixture is called a green anomaly, whilst a man who puts too much red in the mixture is called a red anomaly. The red anomaly is only a trichromic with shortening of the red end of the spectrum, and this may be as extensive as in any case of dichromic vision. I have, however, described trichromic cases who had all the symptoms attributed to the anomalous trichromatics, but they were not anomalous trichromatics as they made an absolutely normal match.[9]

# An Address

ON

# THE POSITION OF SIR CHARLES BELL AMONGST ANATOMISTS.

*Delivered before the Medical Society of Middlesex Hospital on Jan. 19th, 1911,*

BY ARTHUR KEITH, M.D. ABERD., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR AND CONSERVATOR OF THE MUSEUM, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

GENTLEMEN,—In the autumn of 1811, almost one hundred years ago, Mr. Charles Bell, aged 37, issued a little booklet for private circulation in which he expounded an "Idea of a New Anatomy of the Brain." This first account of the theory which revolutionised our conception of the master organ of the body appeared when its author was worried with the minor affairs of life. He was newly married; a few months before he had been at death's door from diphtheria; he had just moved into a house (No. 34) in Soho-square. He was having trouble with his late landlord. His last home (Speaker Onslow's old house) in Leicester-street (square) he had the misfortune to hold on a repairing lease at a rental of £96 per annum. It was this ramshackle old house which Bell selected as a basis for carrying out a frontal attack on surgical London. The surveyor he had consulted assured him it would prove a heavier burden than nine bastard children. Nevertheless, with only £12 in his pocket, he took the house, painted the door oak-colour, fixed on it a green-bronzed knocker, and "engaged a boy for £6 6*s.* a year, giving him a coat and hat," doubtful if he should add a silver band to the latter.[1] When the New Anatomy appeared Bell's late landlord was shouting dilapidations. His museum, his lecture-room, and his two or three house pupils were also moved to Soho-square. There was trouble about the house pupils. Mrs. Bell, as newly married ladies can well understand, wished to share the privacy of her new home with her husband. "You must consider," he wrote to his brother, who acted as Mrs. Bell's ambassador, "that these young men are *house pupils* not *boarders*. Dr. Denman, Dr. Baillie, Mr. Hunter, Abernethy, Cooper, Wilson have had them or have them. Their necessity is understood, they are admitted as being essential to a lecturer." To add to his troubles, when the "Idea of a New Anatomy of the Brain" first saw light there "was an awful pause in regard to patients." He found it necessary to "give up the character of anatomist." Think of being penalised for a priceless discovery. Bell knew Harvey's life and work well; he probably consoled himself by remembering that the discovery of the circulation led to a rapid decline in Harvey's practice.

## WHAT BELL ACHIEVED.

To most medical students Charles Bell is simply known as the man who found out that the anterior root of a spinal nerve is motor in function, the posterior root, sensory. His discovery was much greater than that: he formulated a new theory of the whole central nervous system—a theory which became the basis of our present knowledge. He was the last, and with the exception of John Hunter the greatest, of that remarkable London Scottish or Hunterian school of anatomists which flourished in London from the beginning of the eighteenth until well into the nineteenth century. As an artist-anatomist this country has not produced his superior. The text-book written by John and Charles Bell was not only the best text-book of anatomy of its time, but in the opinion of many is still the most practical treatise on human anatomy yet produced in the English language. He discovered the art of making the structure of man popular with the educated

[1] The chief authorities I have relied on for the facts mentioned in this lecture are the following: "Letters of Sir Charles Bell, K.H.," selected from his correspondence with his brother, George Joseph Bell; London, 1870. "Historical Sketch of the Edinburgh Anatomical School," by Sir John Struthers; Edinburgh, 1867. "Dictionary of National Biography." "Dr. James Douglas and other Medical Biographies," by Dr. Norman Moore. "A History of the Medical Institutions of London," by the same writer, Brit. Med. Jour., 1895, June and July. "Two Great Scotsmen: the Brothers William and John Hunter," by George R. Mather, M.D.; Glasgow, 1893. "The Story of Our Museum and Some of Its Contents," by Dr. C. E. Lakin of Middlesex Hospital, Middlesex Hospital Journal, June—July, 1908.

public. He played a prominent part when medical education was passing through a critical phase in London. During the thirty-two years there, from 1804 to 1836, the hospital schools grew in importance, while the unattached schools sank gradually out of sight. He was one of those who wished to see London supplied with a teaching university, and his name is thus connected with the foundation of University College in 1827. Eight years later (1835) he took an active part in founding the medical school of Middlesex Hospital. The establishment of this school marks the end of the London Scottish school of anatomists.

### BELL'S CHARACTER.

The attitudes of men to their discoveries are as variable as parents to their children. The weak bantling needs a deal of pushing and praise to commend it to the public eye. Harvey and Darwin were ideal parents; having done their best for their discoveries they set them out in the world to rise or fall by their merits, quietly glad when they met with success, and gladly quiet when treated with injustice. That was not altogether Bell's attitude to his discoveries; he knew their merits; his children were as good as Harvey's; the weaker of them he liked best and commended most. One can see from their portraits in our National Gallery that Harvey and Bell differed as widely in features and bearing as in their attitude to their discoveries. The portrait of Bell is by J. Stevens, a Scottish Academician. The picture was probably painted soon after the battle of Waterloo, when Bell was still living in Soho-square and dominant partner in the Windmill-street School, surgeon to the Middlesex Hospital, busily engaged on his brain theory, and just over 40 years of age. In the portrait the powder is combed from his hair and the tail is cut off, events which we know from his wife's letters took place in 1815. From the same source we know he was then "dressing himself young." In 1816 he wore a white waistcoat and green coat. There is more than a little of the dandy in Stevens's portrait. His clever elder brother John was also particular about his dress. A lock is curled flat on the forehead, the hair on the temples is brushed forwards and tinged with grey. The face is chubby, alert, and clean shaven; the mouth small, well formed, and shows determination; the nose has that character we now associate with Pitt and Chamberlain; the forehead is broad; the hands small, finely formed, and manifestly deft. The portrait conveys the impression of an alert man of action, confident of his merits and abilities; there are no signs in it of the patient student, and yet he was a laborious and painstaking student. Like many brilliant men, he had gifts and habits that kept up a constant civil war within him.

### LONDON SCOTTISH SCHOOL OF ANATOMISTS.

Bell had more than a fair share of the merits and peculiarities of the London Scottish school of anatomists. All of them had tastes for the cultured side of life. James Douglas, the founder of the school, who settled in London in 1700 and died in 1742, collected editions of Horace; William Hunter, his direct successor, not only collected rare editions, but works of art and ancient coins; John Hunter shared these tastes; Charles Bell was an artist and critic. He insisted all through his life that artists should seek their inspiration in a study of the living nude as well as in works of ancient masters. All of them became slaves of work and of ambition; a reputation as a scientist was the common aim. Such fees as came their way were used for this. They laboured to give London a world-wide reputation as a centre of medical research. Their discoveries were the only fortunes they designed for coming generations. William Hunter felt himself grievously injured when the Government prevented him from spending his fortune in building a "noble" school of anatomy for national use. John Hunter left a rich museum, a poor family, and a legacy of discovery which the medical world has not yet exhausted. Hewson—if not a Scot, yet of this school—died a martyr to research. Cruickshank died poor. So did Home, and so did Sir Charles Bell. I wonder if any system of State endowment could produce such a school. They were doubly penalised: their researches were costly in money and in time. Their incomes were apt to decrease as their scientific reputations increased. All of them formed collections and museums—expensive necessities for venture teachers of anatomy. Charles Bell had already laid the nucleus of his before he left Edinburgh in 1804; force of circumstances compelled him to part with it in 1828. It was acquired by the Royal College of Surgeons of Edinburgh, where it is still preserved and treasured. In this collection are still to be seen the dissection which James Wilson, Bell's senior partner in the Windmill-street School, made to demonstrate the muscle (compressor urethræ) still known by his name, and the dissection made by Bell to show the internal sphincter of the bladder and the muscular band in the trigone which unites the ureter to the internal sphincter (Bell's muscle). William Hunter's museum was left to the University of Glasgow, Baillie's to the Royal College of Physicians of London, Cruickshank's collection found a home in St. Petersburgh, while John Hunter's, as all the world knows, was purchased by the Government and entrusted to the care of the Royal College of Surgeons of England. It forms the basis of the great collection belonging to that College.

Bell shared the virtues of the London Scottish school, and one rejoices to think he had a fair share of their very human vices. Without exception they were pugnacious men. While careless as to fortune they would fight to the death over a point of priority. The Edinburgh or Monro school shared both their virtues and their vices. Hence the angry quarrels within and between the schools. They were all men deeply in earnest; hence the jealousies, rivalries, and accusations of plagiarisms, and the bitter quarrels which are sure signs of scientific life. They had the unconscious art of making enemies. To peaceful men who believed the medical world and its practice had reached as near perfection as could be in a fallible world they appeared arrogant and disturbers of the medical peace. Charles Bell was bred in the Edinburgh school and spent his life in the London one, and could not be expected to be peaceably inclined. Evidently he had a temper. When he attended the British Association in 1834, then in his sixtieth year, he took an opportunity in his address to remove "a very prevailing notion of the medical men in Edinburgh that I am pugnacious and sarcastic."

We know the inner life of Charles Bell more intimately than that of any other member of the London Scottish school. During the 32 years he lived in London (1804–1836) he confided freely his hopes, his cares, his aims, successes, and foibles to his elder and helpful brother George, who had attained in Edinburgh as high a reputation as a lawyer as Charles had gained in London as a surgeon and anatomist. A selection of these letters have been published; they are most valuable documents, but a harsh critic might use them to an unfair advantage. The letters leave the distinct impression that the writer had been disappointed in his life in London—that he had scarcely been rewarded according to his deserts. Yet those who knew him intimately assure us he was a happy man and enjoyed life. He was apparently one of those men, and they are not uncommon, who is happy and optimistic in speech but sour and pessimistic in writing. The man who is gruff and repelling in conversation is often the most charming letter-writer. Oliver Goldsmith was a genius only when he held his pen. Most men have dual personalities—one of speech, another in writing. Bell did complain occasionally, but Scotsmen must not be taken too literally when they grumble. Complaint is a form of mental luxury. When London had bestowed fortune and fame on William Hunter he wrote to his early guide and friend Cullen, "You have been ill-used at Edinburgh as I have been in London." The particular ill-usage which occasioned this complaint was that the Government did not encourage him to spend his fortune in building a national school of anatomy. Bell had another mental character which distinguishes the real anatomist. His memory and understanding were visual, not auditory; he learned and understood things by seeing them; words alone were poor substitute for things. As a boy Cæsar's bridges across the Rhine appealed to him and so did their construction; the rules of syntax and their able exponent, the rector of the high school, were nightmares.

### BELL'S EARLY DAYS IN LONDON.

So far I have dealt merely with the more superficial and personal aspects of Bell's life and merely outlined his place in the London Scottish school. It is time now to see if the steps can be traced whereby he made for himself a permanent name in the history of anatomy and medicine. Some years ago I inquired into the circumstances which led men to follow the profession of medicine, but amongst the hundred men I then interrogated there were none who were turned to medicine by so strange a chance as the two Bells—John and Charles. Before John

Bell was born, his father, a clergyman of the Episcopal Church of Scotland, had dedicated him to the medical profession, in gratitude for relief at the hands of a surgeon. John Bell was trained under Monro the second, and there was no man in Europe more able to introduce him to a useful study of the human body. In the Edinburgh, as in the London Scottish school, all research and study were bent towards discovering not the form but the *function* of parts. John Bell was a dapper little fellow, of extraordinary ability and personality; he was a splendid draughtsman, clever with his hands and head, clear and quick in speech, a born teacher, intensely practical, independent, and, above all, pugnacious. He set up a venture or extramural school in 1786 when he was 23, won success as a teacher and operator, and was soon at rivalry and war with the privileged authorities of the University. Charles, who was 11 years younger (he was born in 1774), had the same artistic gifts, and followed naturally in his footsteps. Monro was then deep in his researches in the nervous system; he had noted that only the posterior roots of spinal nerves were supplied with ganglia, and one may be quite sure he asked himself and his students the reason of such a distribution. Monro was puzzling over the meaning of the parts and arrangement of the nervous system.

The relationship between the elder and younger Bell is very similar to that between the elder and younger Hunter. John Bell was 11 years older than Charles. William Hunter was ten years older than John. The younger brothers served an apprenticeship in the dissecting-rooms of the elder. The elder brothers were busy teaching and publishing; the younger as busily researching. At the end of the apprentice years the brothers became gradually estranged. At the age of 23 (1797) Charles began his system of dissections and illustrations. By 1800 the quarrels between John Bell and the University had come to a climax. John abandoned the school to Charles; the younger brother had to bear the brunt of the elder brother's quarrels; his way in Edinburgh was barred. Hence the prospecting visit to London in the autumn of 1804. The journey by coach took five days; he reached London on a Sunday and found it dull. The fame of his brother and of himself had gone before him. Their books, writings, and engravings had given them a place in the medical world. Charles was 30 years of age and hoped to obtain a foothold where John Hunter had laboured and become famous. Mr. Anthony Carlisle of Westminster Hospital, six years his senior, told him bluntly they liked to "manufacture their own raw material in London"; Bell's opinion was that "Carlisle has the greatest conceit of himself I ever knew a man to possess." Carlisle's colleague, Mr. Lynn, befriended the able, independent, and ambitious Scot. Was there ever a Scotsman yet who did not meet one Carlisle and many Lynns on his first venture in that strange "cock-pit" of the world—London? In those waiting days Bell rode out with Abernethy, who knew how to cover 22 miles of road at the cost of 1½*d.* for tolls; he dined with Sir Joseph Banks and Dr. Matthew Baillie, and enjoyed gentle flirtations in the agreeable society of Sir William Blizard's daughters. A year passed and nothing came to him, and hence the venture already mentioned of taking Speaker Onslow's old house in Leicester-square with £12 in his pocket and a weekly expenditure that would see his fortune dissipated in a fortnight. An onlooker would scarcely expect that Bell's course was leading towards the discovery of a new anatomy of the brain.

Then comes the opening lecture in the old house at the beginning of January, 1806; it was a wet night and 40 came to hear him, but only 12 enrolled themselves as pupils—bringing him a sum of £82. It was then as it is now: students as a rule do not pay fees to learn the new and the strange; they wish to have clearly set before them the plain and orthodox facts which are needed by them in examinations and practice. Bell was intensely disappointed; he dreamt of hundreds, and not even tens came. The manuscript of the "Anatomy of Expression" which he brought down from Scotland with him was finished in the meantime and published. He was "deeply mortified" when Mrs. Sydney Smith suggested it would be better to have someone to remove the Scotticisms. However, the book succeeded, and it deserved its success; it is the first and greatest of any work on anatomy for artists that has seen the light of day in this country.

## WORK ON THE ANATOMY OF THE CENTRAL NERVOUS SYSTEM.

A study of how the emotions are expressed in man led him towards the brain. No explanation could then be given of the division of this organ into lobes, nor was any particular functional meaning attached to the cerebellum. The cranial nerves were complicated in their distribution and course, and the spinal nerves had two roots just because they had been created so. On the theory of the brain then taught, a single nerve should have been sufficient for each part; one kind of nerve was enough for all kinds of sensations and impulses; the nerve path which served to bring a message to the brain also sufficed to take one away again. Bell was a close student of John Hunter's works; Hunter was his ideal; he must have known that Hunter had discovered the double nerve-supply of the olfactory mucous membrane, and that he explained the fact by supposing the first nerve was only for the sense of smell and the fifth for ordinary sensation. Hunter suggested that there were different kinds of nerves—those of the eye, the nose, and of the ear were for the transmission of special forms of sensation, and those like the fifth for ordinary sensation. This much at least is clear: the starting point of Bell's discovery was the recognition that the optic nerve transmitted only impressions connected with sight, the olfactory only with smell, the auditory only with hearing, the gustatory only with taste. There were therefore different kinds of nerves; all nerves were not functionally alike. Another of Hunter's observations may have influenced him. When a joint is flexed it was Hunter's opinion that the extensor or elongating muscles were as directly under the control of the nervous system as the flexor or contracting muscles. Bell went a step further; from his own sensations he was convinced that the muscles must be as freely supplied with nerves of sensation as with nerves of motion—a conception which Sherrington has elaborated and extended with unrivalled skill. In Bell's opinion our muscular actions were controlled from beginning to end on the impressions carried to the brain by the sensory nerves which supplied them. He could not conceive that one nerve could carry messages to and from the brain simultaneously; there must be two paths. The problem of the two roots came back to him: was it possible one was for sensation and one for motion? The nerves from the organs of sense, which he knew to be purely sensory, ended in the dorsal or posterior columns of the nerve axis; when he followed up the anterior roots he traced them in the anterior columns of the cord to the pyramidal tracts, crusta, and cerebrum; the posterior roots he found went by the posterior columns to the cerebellum. Therefore the brain and the anterior or ventral parts of the nerve axis were connected with motion; the cerebellum and the dorsal parts of the cord and medulla were connected with sensation. That was the theory he set out to prove in 1807—the second year of his venture lectures in Speaker Onslow's old house.

In 1808 he had exhausted the anatomical evidence and tested the truth of his inference, drawn from anatomical evidence, by physiological experiment. The experiments were confirmatory, but in his opinion not altogether decisive. To reach the spinal roots and cord entailed a considerable injury to the parts operated on. If his theory were true, he inferred that it should also be applicable to the cranial nerves. There the nerves were more superficial, and it was possible to select examples in which the sensory and motor roots were not conjoined. He selected the seventh as a type of the anterior or motor nerve, divided it, and found the facial muscles were paralysed; he exposed the fifth (he did not then know of its motor root), divided some of its branches, and found common sensation was lost. Until these experiments were made the facial and fifth nerves were supposed to fulfil the common purpose of nerves. Up to Bell's time the only explanation offered for the double nerve-supply of the face was one supported by his old teacher Monro—that the fifth might still act if the facial nerve was accidentally injured or *vice versâ*. The discovery of the cause of facial palsy was a side issue; the importance of the experiment to Bell was that it demonstrated the truth of his theory from one end of the central nerve axis to the other. The ventral part was motor, the dorsal sensory.

Bell's second discovery—the recognition of a respiratory system of nerves—came about in the following way.

About 1813, the year after he joined Wilson in the Windmill-street school, he made a dissection of that complex of nerves which may be exposed between the mandible above and the thorax below. He had to demonstrate them to his class next day. What explanation could he give that would account for the intricate manner in which the cranial and cervical nerves were arranged and distributed in this region? Many of these nerves—the ninth, tenth, and eleventh—did not arise either in the line of his sensory or motor roots, but intermediate to them. Why was that? He had to go to a case in the country, and on the way he discovered what he believed to be the explanation. The chief nerve of the group went to the lungs; it was functionally therefore a respiratory nerve. The other nerves arising in line with it—the sixth, ninth, and eleventh—must also be respiratory. The muscles of the face were, in his opinion, mainly respiratory in function; the sterno-mastoid supplied by the eleventh could be used in inspiration. He was dominated by the idea that the origin of nerves must be determined entirely by function. The mechanism of respiration, he believed, had been added to the more primary actions of the body and the system of nerves which regulated it must have been interpolated in the motor and sensory systems. He supposed that an intermediate system must be represented in the cord to influence and control the respiratory action of the body wall muscles. The phrenic (internal respiratory nerve) and long thoracic (external respiratory nerve) he also supposed to belong to this system. Bell was particularly fond of his "respiratory" theory. It was the first attempt ever made to explain a certain series of complicated facts. He saw that nerves having an intermediate root origin must be different in nature from the nerves rising in the dorsal and ventral series. We had to wait 60 years before a more satisfactory explanation was given of the nerves which have an intermediate root origin. It came with the demonstration of the splanchnic system by Gaskell. But who can yet explain why the sensory system is dorsal, the ventral motor, and the intermediate splanchnic?

### COMPARISON OF DISCOVERIES OF HARVEY AND BELL.

There is a remarkable similarity between the discoveries of Harvey and of Bell. Monro, as we have seen, was puzzling over the meaning of spinal ganglia when Bell was a student in Edinburgh at the end of the eighteenth century. Fabricius was trying to explain the meaning and use of valves in the veins when Harvey was studying in Padua at the end of the sixteenth century. They were designed, Fabricius thought, to secure an even distribution of the blood during its reflux from the thorax to the extreme parts of the body. Harvey and Bell came to London to observe, reflect, and experiment, and teach and practise for a livelihood. Harvey brooded over his "new" idea from 1616 to 1628 before publishing; Bell over his from 1807 to 1821. Harvey found the arrangement of valves could not be explained on the current teaching of the day. They allowed blood to pass only in one direction, and that was towards the thorax. The current teaching could offer no explanation of why the lungs required a special ventricle and an artery as big as that to the whole body for their special blood-supply. No explanation was offered for the existence of the tricuspid valve, nor for the semilunar and mitral valves. Harvey was the first anatomist to formulate as a working principle for the investigator that the existence and form of every organ and part of the animal body is determined by function, and that by a study of form a key or guide may be obtained which will direct the inquirer as to the manner in which the function may be experimentally demonstrated. A rational study of anatomy guided Harvey and Bell to their discoveries.

On whatever standard one proceeds to judge, Charles Bell must be assigned a first place amongst the world's anatomists. He did for the anatomy of the nervous system what Harvey did for the circulatory system—brought order out of chaos. John Hunter was probably a greater discoverer than either, but he was an anatomist of life rather than of the human body. Harvey proved his thesis in every point; his demonstration was complete. His inclinations were under the sole guidance of his facts. Bell, as we have seen, sometimes allowed the facts to follow his inclinations. In Bell's favour we must take into consideration he was dealing with the most complex and elusive system of the body, one which can be interrogated with success only by the more delicate modern means which Bell had not at his command.

In conclusion, I cannot do better than quote to you a footnote from Sir Charles Bell's treatise on the "Nervous System of the Human Body": "In your department," Sir Humphry Davy said to him, "you can hope for nothing new. After so many men in a succession of ages have laboured on your subject, no further discovery can be expected." "This," writes Bell, "shows great ignorance of anatomy since every improvement points to something new, and the higher we go the more is the field of view extended." Once a new path is found there is no telling the various discoveries it may lead to. The path discovered by Charles Bell is one which has carried his successors into new and wide fields. Nor are the methods which Harvey and Bell employed to elucidate the human body exhausted; those who know the structure of man best know how obscure are many parts and organs of the human body, and how indifferently they can be explained on the basis of our current teaching.

## THE TREATMENT OF EXTENSIVE CARIES IN CHILDREN BY EXTRACTION.

BY J. F. COLYER, M.R.C.S. ENG., L.R.C.P. LOND., L.D.S. R.C.S. ENG.,
DENTAL SURGEON TO CHARING CROSS HOSPITAL; DENTAL SURGEON TO THE ROYAL DENTAL HOSPITAL, LONDON.

FOR several years it has been my practice to treat extensive caries in children by extraction. The principal criticisms brought against this method of treatment have been: (1) that the loss of mastication area interferes with the growth of the child; and (2) that the effect on the permanent series is to cause irregular eruption and crowding of the teeth. I propose to show that these criticisms are not altogether supported by facts, and that the effect of the removal of the teeth on the general health of the child is beneficial rather than harmful; still further, that the harm accruing to the permanent series is slight and well outweighed by the gain to general health.

The treatment, briefly stated, consists in the removal of all functionless deciduous and permanent teeth. To consider the question more in detail. If the first permanent molars are in position the best treatment seems to be the removal of all the deciduous molars. I do not hesitate to remove sound molars if their antagonists have been removed. For example, suppose the right maxillary deciduous molars and the left mandibular molars are unsavable, and their removal is called for, then the remaining teeth—namely, the right mandibular and the left maxillary molars—are rendered functionless and can serve but little good purpose; indeed, they will harbour food, and so prevent the mouth being kept naturally clean. It is urged that such treatment robs the child of masticating power, but such teeth are useless as far as the function of mastication goes; indeed, they render the first permanent molars functionless, because a child with tender teeth "bolts" food and cannot chew.

In cases where at, say, the age of 8 years the first permanent molars are carious and have exposed pulps or septic pulps, these teeth are removed in addition to the deciduous molars, the child being left with only the permanent incisors and the deciduous canines. The improved condition of the child following this rather drastic treatment can best be shown by detailed reference to a few cases.

CASE 1.—A female patient, aged 4 years and 6 months, when first seen was suffering from gastro-intestinal trouble.

Teeth removed[1]: $\frac{d\ c\ b\ a}{e\ d} \Big| \frac{a\ b\ c\ d}{d\ e}$

In this case the $\overline{e}\,|\,\overline{e}$ were not carious and are being retained until the $\overline{6}\,|\,\overline{6}$ erupt, when they will be removed. This patient has lost her gastro-intestinal trouble, and between June 8th and Oct 2nd she increased in weight from 2 st. 4 lb. to 2 st. 8 lb. The normal weight should have been about 2 st. 8 lb. and the normal increase in four months about 1½ lb. This patient, however, increased 4 lb.

[1] The notation used is that usually adopted in dental literature. The letters and figures above the line indicate the upper teeth, those below the line the lower teeth. The figures on the right hand denote the left teeth, and those on the left hand the right teeth. The numerals are used for the permanent teeth, and the letters for the deciduous teeth. The teeth are counted from the middle line. Example: $\overline{6}$ indicates the left maxillary first molar; $\overline{e}$ the right lower second deciduous molar.

CASE 2.—The patient, a male, aged 7 years and 4 months, was stated always to have had indigestion.

Teeth removed: $\frac{6\ e\ d\ c}{6\ e\ d\ c} \Big| \frac{c\ d\ e\ 6}{c\ d\ e\ 6}$

The teeth were removed on Dec. 6th, 1909, the patient weighing 3 st. 2½ lb. On Feb. 7th, 1910, the patient had increased to 3 st. 5 lb., and all symptoms of gastro-intestinal disturbance had ceased. The average weight of this boy should have been about 3 st. 9½ lb. and the increase in two months a little under 1 lb. The weight, however, increased in two months 2½ lb.

CASE 3.—The patient, a male, aged 6 years and 7 months, complained of constant feverish attacks.

Teeth removed: $\frac{e\ d\ b\ a}{e\ d} \Big| \frac{a\ b\ d\ e}{d\ e}$

Between December, 1909, and Oct. 23rd, 1910, the weight had increased from 3 st. 5 lb. to 3 st. 10 lb. The feverish attacks had ceased and the child now slept and ate well. This patient was of about average weight, and the increase in weight was about normal.

The rapid increase in weight following the extraction is at times very marked. For example, in a boy, aged 10 years and 2 months, who was suffering from "glands," it was found advisable to remove: $\frac{e\ d\ c}{e\ \ c} \Big| \frac{c\ d\ e}{c\ d\ e}$. Between June and October this boy increased in weight from 4 st. 6 lb. to 4 st. 11 lb. The normal weight should have been about 4 st. 11½ lb., and the average increase in four months about 2 lb. This child in this period in-increased 5 lb.

CASE 4.—The patient, a boy aged 6 years and 6 months, when seen on Nov. 28th, 1910, was found to be suffering from "glands," gastro-intestinal sepsis, and general ill-health. He weighed 2 st. 12 lb. The first permanent molars were partially erupted. The following teeth were removed: $\frac{d\ \ b\ a}{e\ d\ \ b\ a} \Big| \frac{a\ b\ \ d}{a\ b\ \ d\ e}$. The $\underline{e} \Big| \underline{e}$ were carious but the pulps were not involved and they are being retained until the $\underline{6} \Big| \underline{6}$ are fully erupted. This patient was seen on Jan. 16th last, when he weighed 3 st. 3½ lb., and therefore showed a gain of 5½ lb. in about seven weeks. His mother stated that his appetite showed marked improvement. The glands were considerably smaller. The increase in weight is, however, not always shown; in a few cases there is a slight decline, but this is, I find, frequently traceable to the presence of sepsis in some other parts—for example, the tonsils or the naso-pharynx.

To show how the effect of tender teeth will affect the child the following case is of interest because the mother had kept a regular record of the child's weights.

CASE 5.—This child from birth had increased progressively in weight until September, 1909, the weight at that time being 24 lb., and the age of the child 3 years. The mouth then began to get tender, and in February, 1910, the child had lost 1½ lb. The deciduous molars were removed and attempts were made by local treatment to conserve the incisors. Within one month this child had increased to 24¾ lb. By Sept. 3rd the weight was 27½ lb. The incisors now began to give trouble, and the child when seen on Oct. 6th weighed 25¾ lb. These teeth were removed with the following results: Oct. 6th, 25¾ lb.; 15th, 26¼ lb.; and 29th, 26⅝ lb.

One further case may be given because it emphasises the point that when the increase in weight does not follow the removal of the teeth there may be other sources of sepsis present.

CASE 6.—The patient, a female, aged 7 years and 6 months, when seen on Feb. 23rd, was suffering from defective teeth, tonsils, and adenoids. The following teeth were removed: $\frac{6\ e\ d\ c}{6\ e\ d} \Big| \frac{c\ d\ e\ 6}{d\ e\ 6}$. The following records of the child's weight were taken:—

| | st. | lb. | oz. | | st. | lb. | oz. |
|---|---|---|---|---|---|---|---|
| Feb. 23rd ... ... | 3 | 10 | 8 | May 25th ... ... | 3 | 9 | 12 |
| March 24th ... ... | 3 | 9 | 12 | July 26th ... ... | 3 | 10 | 12 |
| May 3rd* | | — | | Oct. 15th ... ... | 4 | 0 | 6 |

* Tonsils and adenoids removed.

In this case the improvement in weight and general health did not follow until the complete removal of the sources of sepsis.

The cases quoted are sufficient evidence that the loss of masticating power does not interfere with the general health of the child, but increases the power of metabolism by removing a source of sepsis. Having shown that a marked improvement in the general health follows the treatment of free removal of the teeth, it will now be necessary to deal with the influence of the treatment on the growth of the jaws and the eruption of the teeth. It has been urged that the removal of the deciduous molars allows the first permanent molars to come forward and so cause in the future crowding of the anterior teeth. With regard to this, I would point out that such travelling forward of the permanent teeth occurs mainly in mouths where the growth of jaws is interfered with by want of function, either due to insufficient mastication or lack of nasal breathing. From observation—but I express myself guardedly in this respect—I am inclined to think that if, by removing the deciduous molars, you can render the first molars functional, the growth of the jaw will be stimulated and room made for the development of the second and third molars, with no forward pressure from these teeth, and, with the first molars occluding correctly, there will be little, if any, forward movement.

A somewhat extended experience of these cases seems to show that the first molars move forward but little, if at all, in children who have been free from adenoids, and in whom at the time of removal the first permanent molars are in correct occlusion, and the teeth are in their normal vertical direction. On the other hand, in children who in their early years have suffered from adenoids, the first molars do move forward, but in these cases the forward movement always occurs, although perhaps it is less marked, directly the second deciduous molars are lost in the natural way. But granting that the treatment of extraction suggested does cause a moving forward and subsequent crowding, the removal of four teeth will easily alleviate the condition. One has to weigh in the balance the loss of four teeth against the constant presence of oral sepsis and all its sequelæ. In my opinion the former far outweighs the latter. Take as an example the following case.

CASE 7.—The patient, aged 8 years, was suffering from general ill-health and chorea. The deciduous molars were removed, and with the eruption of the premolars the teeth presented a slightly crowded condition. The second premolars were removed and the child has now a good regular arch and an excellent occlusion.

In this case there is no proof that a crowded arrangement of the teeth would have been avoided by the retention of the deciduous molars, but even granting that it would have been, which was the better line of treatment—a septic mouth for four years, with the possible chance of preventing crowding, or a clean mouth for four years and the risk of crowding, which can be easily remedied?

The drastic removal of teeth does not lead in the majority of cases to any marked irregularity on the eruption of the permanent teeth. Indeed, it is surprising what excellent arches are eventually met with in these children. In cases where the majority of the deciduous teeth have been removed before the age of six years the permanent incisors erupt in a regular arch, and one rarely finds any "spreading." Again, in cases where the first permanent molars and the deciduous molars have been removed, perhaps before the age of nine years, an excellent occlusion will usually follow. In a few cases the happy results just referred to do not always follow, but in these the trouble is often traceable to asymmetrical extraction.

A word now in reference to the treatment of cases where the teeth are decaying on all surfaces, such as occurs from the sucking of sugar-bags, or the constant presence of an easily fermentable carbohydrate on the surface of the teeth. Providing the pulps of the teeth are living, we can hope to arrest the caries by placing the teeth under a proper environment. It is a *sine quâ non* of the treatment that mouth-breathing, if it is present, should be cured. Careful regulation of the diet and cleansing of the teeth, combined with local treatment, will sometimes work wonders. For the latter purpose no drug acts better than nitrate of silver, and this should be applied to all the carious surfaces of the teeth at least once a week until the dentine shows signs of hardening. The arrest of the condition can also be applied by the regular use by the parents of spirits of wine and an alkali.

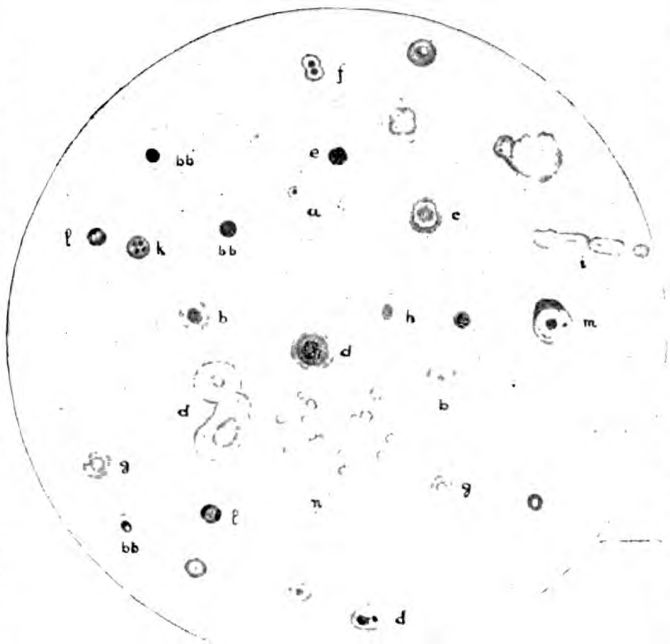
# X BODIES IN HUMAN BLOOD.

BY ANDREW BALFOUR, M.D., B.SC. EDIN., F.R.C.P. EDIN., D.P.H. CAMB.,
DIRECTOR, WELLCOME TROPICAL RESEARCH LABORATORIES, GORDON COLLEGE, KHARTOUM.

As noted in the first Review Supplement of our laboratories, these curious bodies had once been noted in the blood of a sick dog in Khartoum. On Nov. 23rd, 1910, I received the following report, accompanied by the blood films mentioned, from Dr. Nicola Mâloüf, of the Sudan Medical Department, one of the medical officers in Omdurman, who, when in Khartoum, had been diligent in his attendance at the laboratories:—

"I am sending you four slides of blood from a patient under my care who is suffering from a very interesting disease, which I might call urticaria nocturna. The disease is of four months' standing; it appeared at Kamlin. The patient is a white lady about 18 years old, married, and is nursing a child 1 year old; the child is very healthy. The case presents the following symptoms. Every evening about 7 P.M. flat, solid, more or less elevated wheals, irregular in size and shape, begin to appear all over the body. These wheals disappear and others appear till the early morning, when the eruption begins to diminish, and about sunrise nothing is left and the patient looks normal like any other person. The eruption is accompanied by a severe itching and burning sensation; there is no fever and no disturbance of any of the systems of the body. The lady has lived in Kamlin for the last two years. The slides are not fixed. Will you kindly examine them for anything you might think as a cause? If more slides are required, or any other information is necessary, I will be very glad to help."

Inquiry elicited the fact that at no time had there been any fever.



Illustrating X bodies in the blood. × 1000.

In one of the films I found typical X bodies in considerable numbers, free and occasionally lying on the red cells. A fairly common form was the small body (see Figure, *a*), which Horrocks and Howell[1] describe as being about one-eighth the size of a red corpuscle, spherical in form, and consisting of a faint capsule with a circular centre staining deep blue. The majority, however, had centres more of a pale lilac than a blue colour, and contained faintly staining material between their capsules and their centres (*b*). What may be called large and intermediate forms (*bb*) of a similar type were present, but in the former the capsule was not so defined, the appearance being rather that of a halo of more faintly staining substance surrounding a deeply stained spherical core (*c*). Very few forms with concentric ring (*d*) were observed; and only one or two of the large "solid" coccus-like type (*e*) shown in the drawing "A" which so well illustrates the paper by Horrocks and Howell. One did not see the type with an indented centre, crescent-shaped, and enclosing a small circular body, of which they speak, but the forms apparently in process of division were present (*f*). I am not sure that these, especially when occurring in groups of threes, do not really represent fused forms. Bodies which may be described as fragmented were encountered. Some of these have only a chip, as it were, broken from them, or look like biscuits from which one has bitten out a piece (*g*). Distinctly oval forms were seen, usually of considerable size (*h*), and also a curious oblong appearance which it is difficult to describe, but which is well shown in (*i*). There can be no doubt these forms consist of the same substance as the bodies. For convenience I will call them the oblong forms. Again, small forms measuring 3 $\mu$ in diameter were met with, one of which showed a segmentation of the central spot into four (*k*); another no dark centre, but dark spots at its periphery (*l*); and yet another a kind of inner capsule. Many of the smallest forms were homogeneous, showing no dark centres whatever, while some of the larger forms, with distinct cores, showed granular material between their capsules and their centres. In this there were sometimes small blue spots or granules. Others, again, were irregular in shape, being what may be called "knobbed" bodies (*m*).

Like Horrocks and Howell, I found no trace of chromatin in these bodies; but I noticed that, lying free, there was a considerable amount of amorphous-looking material which ook on a pale lilac stain like some of the smaller bodies. This was more plentiful in that part of the film where the bodies occurred, for I did not find them equally distributed throughout, and I could not help thinking that there was some connexion between the bodies and this material—i.e., that they might represent portions of it which, owing to the action of the circulating blood, had assumed a spherical shape just as do fragments of macrophages. Still, it was difficult to account for the concentric rings on this hypothesis, and altogether I found it impossible to come to any conclusion regarding them. At the same time further study convinced me that the smaller homogeneous bodies at least, whose staining reactions and definite form readily distinguished them from blood plates, are in reality derived from the irregular amorphous masses. One can, as it were, see them budding and breaking off from the latter, which themselves are very curious and interesting, containing, as they often do, an irregular central cavity, and being furnished with edges which resemble the outline of a very rugged and indented sea coast (*n*).

The following are the measurements of the various forms of bodies found:—Spherical: These ranged from 0·7 $\mu$ to 5·25 $\mu$ in diameter; 1·5 $\mu$ was common, and 2·25 $\mu$ even more so, the majority being of this dimension. 3 $\mu$ and 3·3 $\mu$ were, however, not at all rare. Fused or dividing forms frequently measured 3 $\mu$ each. This was also the size of some small "solid" coccus-like forms, four of which were found lying close together. One so-called oblong form measured 6·75 $\mu$ in length by 3 $\mu$ in breadth; and another, which lay end-to-end with it, 4·5 $\mu$ by 3 $\mu$.

It will be seen, then, that the bodies are pleomorphic, although quite distinct from all the blood elements and readily recognisable as specific entities. As I only found them in one film out of the four sent, it occurred to me that their habitat might not be the blood but the skin, from which they may have been washed out by the first drop of blood. I had no means of telling which was the first film taken, but I noted that Horrocks and Howell on several occasions found

[1] Horrocks, W. H., and Howell, H. A. L. (April, 1908): X Bodies found in the Blood of Human Beings and Animals, Journal of the Royal Army Medical Corps, vol. x., No. 4.

the bodies in one slide out of several examined. On the other hand, this was by no means their invariable experience, while they once recovered the bodies from broth into which a piece of the liver of an ox or cow had been placed. This would appear effectually to dispose of the idea that they are derived from any part of the skin, unless some contamination had occurred.[2] The same remark applies to their successful inoculations of rabbits.

I asked Dr. Mâloüf to send me some more blood films, and he forwarded ten, all unfortunately taken from one of the urticarial wheals and numbered in the order in which they had been taken. In none of them were X bodies found. The previous blood films had been made from finger blood. I now sent Dr. Mâloüf two tubes of Nicolle's blood agar and several tubes containing the 1 per cent. sodium citrate solution employed by Horrocks and Howell, and requested him to inoculate these tubes with appropriate quantities of blood taken from the finger as at first. This he kindly did, and I incubated the inoculated media at or about 22° C. The tubes were examined daily for five days, care being taken to secure the blood sediment from the citrate tubes. Unfortunately coccal or bacterial contamination, apparently of cutaneous origin, eventually made its appearance in every one of the tubes, and at no time were any X bodies found. I tried hard to get the patient to visit the laboratories, but in vain; and before Dr. Mâloüf could obtain other films or make other blood cultures she left for Kamlin on the Blue Nile. Hence, much to my regret, I was unable to pursue the case further or to confirm the findings of Horrocks and Howell in culture media, or to repeat and extend their inoculation experiments.

Although one cannot express any opinion on these curious bodies their occurrence in the Sudan is certainly interesting, as is the fact that they were found in a case unassociated with fever, but suffering from a recurrent or intermittent urticaria. I am indebted to Mr. George Buchanan, our senior laboratory assistant, for the careful drawing illustrating the main types present.

Khartoum.

## SOME CASES ILLUSTRATING THE EFFECTS OF THE HYPERÆMIA TREATMENT BY ELASTIC BANDAGE ON UNUNITED FRACTURES.

BY ARTHUR E. BARKER, F.R.C.S. ENG.,

SURGEON TO UNIVERSITY COLLEGE HOSPITAL, AND CONSULTING SURGEON TO THE QUEEN ALEXANDRA MILITARY HOSPITAL, MILLBANK, S.W.

TROUBLESOME cases of ununited fracture are constantly occurring in surgical practice and tax our resources to the utmost in bringing about their repair. The condition appears to be met with after any kind of fracture of the long bones, from the most simple and limited to the most extensive comminuted and compound varieties. The various causes are fairly well recognised now and need not be alluded to, the object of this communication being merely to report cases in which a very simple method of treatment was followed by the best results where other more serious measures had failed. The treatment is not new, but though it has been in favour with some for many years it does not appear to have as yet gained for itself that place in ordinary surgical procedure to which it is entitled.

The method of inducing union in ununited fractures by engorging the parts around by bandaging above and below the lesion appears to have been first proposed and practised by Mr. Thomas of Liverpool many years ago. This is pointed out by Bier in his valuable treatise on the uses of artificial hyperæmia in surgery, which has done so much to enlarge our views on the processes of repair in many ailments. But so far the practical use of hyperæmia, as applied to ununited fractures, does not appear to have become general, as remarked above.

When a simple, say transverse, fracture of the tibia (e.g., Case 2), put up and maintained in perfect position, is found at the end of six or eight weeks quite ununited, several other facts about the limb may usually be noticed as well. It is, of course, flabby, and more or less wasted from disuse; it is colder than its fellow, and, as a rule, the skin is paler. The necessity for complete immobilisation is the cause, and prevents us from employing massage or any of the usual means for keeping up the normal nutrition of the limb. This may, of course, in exceptional cases, have been further impaired by needlessly firm bandaging. But apart from this mere disuse produces a greater or less amount of anæmia in the injured area, although at the first there is a certain degree of traumatic hyperæmia, the first step in the process of repair.

It seems, therefore, quite a common-sense measure to create by mechanical means an increased flow of blood through the part. This was often done in earlier days by forcibly rubbing the bones together and so reproducing a traumatic hyperæmia. But the objections to this were obvious, the chief one being the difficulty of replacing the bones in good position. The use of the elastic bandage is now found to be equally efficacious or more so. In the cases below it was applied lightly over the limb below to within a couple of inches of the fracture and more firmly above downwards to within the same distance of the lesion. The only difficulty met with is in producing the necessary amount of engorgement without interfering with circulation in the deeper parts. The upper bandage had often to be readjusted more than once to obtain the blue-pink flush *without* pain, which should always be present. Any pain or absence of circulation in the interval between the bandages was always a reason for the removal of the upper one. The engorgement was kept up about two hours morning and evening, and in the intervals the whole limb was wrapped up in warm wool.

In the last case in our group, in which necrosis of the ends of the bone had taken place as the result of the laceration of the soft parts and the periosteum by the injury, another effect of the engorgement was in play. The sinus left after removal of the sequestra was presumably more or less infected, although the temperature for weeks had been quite normal. Here the first effect of the constriction hyperæmia was always to produce an increased flow of serum, and it is fair to assume that any organisms present were mechanically carried out of the sinus. But besides this, the germicidal effects of the healthy serum resulted soon in a perfect cleaning of the granulating track. The net result was a rapid healing of the whole wound. The gradual formation of abundant callus could be followed by skiagrams after this until union was sound. Since then active exercise has been encouraged in every way, and the limb has been massaged to improve nutrition and get rid of the stiffness naturally following such prolonged disuse.

It will be noted that in the first case recorded here two attempts to secure union by wiring had failed, and though abundance of time had elapsed after the last operation to allow of the formations of callus no repair had taken place. It was only when the hyperæmia had been kept up for some time that this result was obtained and union became solid.

The last case was a particularly serious one. For it was the patient's right arm, and a second wiring was not considered desirable in view of a state of ulceration, necrosis, and sinus remaining after the original injury. The removal of the sequestra besides left a gap between the bones and a granulating cavity. In this case all that was done was to place a thick rod of aluminium within the medullary cavity of both ends so as to keep them in a straight line. The two pieces were pushed together over this and nothing further was done to hold them together. A small gauze drain was inserted down to the line of fracture and the wound was partially closed. What remained healed with remarkable rapidity under the increased hyperæmia induced by the bandage and our radiograms showed how quickly callus began to form after this. It may be suggested that all this would have taken place without the bandage. Perhaps it might. But the fact remains that no trace of repair of the bone could be made out until the hyperæmia had been in full swing for 10 for 12 days, when our patience was nearly exhausted. Moreover, the same result was obtained in the two practically simple fractures, Cases 2 and 3, which had failed to unite under conditions which

[2] Mr. George Buchanan, however, drew my attention to the fact that some of the forms were present on the slide beyond what one may call the "commencement end" of the blood film. This rather suggests that they may have been derived from the surface of the skin, especially as, in all probability, the slide was pressed down upon the finger in order to take up the drop, and not merely allowed to come in contact with the latter.

were more than usually favourable. The bandage was applied when surgeon and patient were beginning to lose heart: the effect was rapid union.

CASE 1.—The patient, a man, aged 37 years, was admitted on Nov. 4th, 1905, for a compound comminuted fracture of the right humerus at the junction of the lower and middle third with a subcoracoid dislocation. There was a wound on the inner side of the arm from which much blood was oozing. The main line of fracture ran from above downwards, forwards, and outwards. Another plane of fracture ran downwards and inwards, cutting the other plane at about its upper third and separating a triangular fragment from the shaft. The lower pointed end of this separate piece was broken off by a third line of fracture. Under chloroform the dislocation was easily reduced and the rather pointed ends of the main fragments were wired together and some small fragments and débris removed. The incision which had been made through the fracture wound was partly stitched up and the rest drained with aseptic gauze. The first couple of days a large quantity of clear brownish discharge came away followed by a fall of temperature, which had been high. After this the wound steadily closed and he left hospital nearly healed, the arm being still in splints. Healing was complete at the end of December.

On March 5th, 1906, he was readmitted looking well and wound soundly healed. But the fracture was ununited, and a radiogram showed much displacement and that the triangular fragment mentioned in the first notes had slipped in between the end of the upper and lower main portions of the humerus.

On March 8th I opened up the old scar, removed the wire and the intervening loose but still living triangular fragment, and "scarfed" the ends of the main upper and lower bones, and united them with two wires in good position. The wound did very well and the patient went home on March 31st.

On Oct. 24th the patient was readmitted, and it was thought that the union was sound. It was also found that the head of the humerus had again slipped out and lay under the coracoid. During some attempts to reduce the dislocation, which failed owing to firm adhesions, the fracture was found to be ununited. The head of the bone was resected and the arm put up straight. This wound healed quite satisfactorily, but the fracture did not unite for some months. The Bier's bandage was then applied when he came up daily during a holiday which I had, and on my return I found it firmly united.

CASE 2.—A man, aged 56 years, was sent to me a year ago for transverse fracture of the tibia. This had occurred in the hunting field from the kick of a neighbour's horse and was compound. He had been admirably dressed and the limb put up in splints by Dr. H. Fraser of Harpenden. I had little to do but to cleanse the wound, cover it with boric lint, and put the leg in side splints. The wound healed without reaction and the splints were, at the end of eight weeks, put into a Croft's plaster apparatus. Union had not taken place when the patient went to Brighton. I requested the surgeon under whose care I placed him to remove the Croft in a week or two and report progress. This he did and told me there was no union. I then asked him to use Bier's bandage and report further. This he did a few weeks later, informing me that the tibia was firmly healed.

CASE 3.—The patient, a man, aged 44 years, was admitted for transverse fracture of the left humerus a little above the middle, which was ununited. He had sustained the fracture three and a half months before from a fall on the shoulder. The arm was in splints until a week before he came in and was then found, after passive movement, to be ununited. The ends of the bone were found to be in good position, but there was very little surrounding callus. On the next day I applied Bier's bandage above and below the fracture for about one hour each day and later for one and a half hours twice a day. On April 10th the note is that "union seems to have taken place." The hyperæmia was continued as before. On April 29th the union was quite sound and the patient went home.

CASE 4.—A young man, aged 21 years, fell from his bicycle in Suffolk on July 24th, 1910, and sustained a bad transverse fracture of the right humerus with much laceration of periosteum and soft parts, and with extensive subcutaneous and intramuscular bleeding. He was put up with an aseptic dressing and splint and sent up the next day to University College Hospital. Position was good, but it was doubtful whether asepsis had been secured. There was an open wound on the front and inner side of the middle of the arm, which, after the usual cleansing and painting with tincture of iodine, was enlarged. Much laceration and blood clot were found and a transverse fracture. This was wired firmly in excellent position and the wound was closed. It was necessary to let go a couple of stitches a few days later as there was a considerable amount of altered blood clot and turbid serous effusion and rise of temperature. After this the temperature fell to normal and remained so until the end of the case. The wound, however, continued to secrete and the bone failed to unite. When I returned from my summer holiday it was still without callus and there was a small sinus. A radiogram showed that a small portion of both ends had necrosed. The wound was now opened up on Sept. 29th, 1910, sufficiently to remove the sequestra and the loosened wire. A rod of aluminium was then placed between the two ends in the medullary cavity to keep the fragments in line, but they were not further secured by wire, being simply forced together over the metal rod. At the end of ten days, when the stitches had been removed, the elastic bandage was applied for two hours morning and evening. The first effect was to increase the flow of serum from the sinus and to help to its rapid closure. Soon after the bones began to knit and a skiagram showed the formation of callus. Union was soon firm and the patient is now exercising his arm and is having massage to remove the stiffness and muscular atrophy following disuse. The radiograms now show a fair amount of callus which is on the increase; also that the aluminium rod has gravitated downwards somewhat, and, what I cannot explain, has escaped from the medullary cavity of the lower fragment.

To sum up, it may be accepted as fairly certain that, excepting the interposition of fragments of detached bone, of muscles or tendons, or of stripping of periosteum, the chief cause of delayed or completely arrested union of fractured bones is lack of proper circulation in the area injured. This may be due to rupture of the arteries supplying the bones, to over-tight bandages when the splints are applied, or, above all, to disuse. If the vascular supply is damaged it is plain that we cannot repair the condition. But we can further impair the proper blood-supply by improper bandaging. This is avoidable. As to disuse, as long as the fracture is insecure it is difficult to make any use of the muscles of the limb. If we could it is probable that such fractures would rarely fail to unite. We know that broken ribs, which are always in a state of movement, hardly ever remain ununited. I have never seen a case or read of one. When then for any of the last causes mentioned repair has not taken place, it is natural to turn to mechanical measures to increase the hyperæmia of the parts involved. In the past we know that this has been done, either by forcibly rubbing the fractured ends together to excite a fresh traumatic hyperæmia, or by pegging the bones with ivory nails or by massage. These measures have succeeded in many cases and failed in others, in the last case often on account of suppuration. It is only claimed for the elastic bandage that it produces a greater vascularity of all the parts involved easily and without risk if properly done.

The question how long it should be kept up is variously answered. In my own experience all the effects desired have been obtained by the use of the bandage for about two hours morning and evening.

Two of these cases have been shown at the Medical Society.

Harley-street, W.

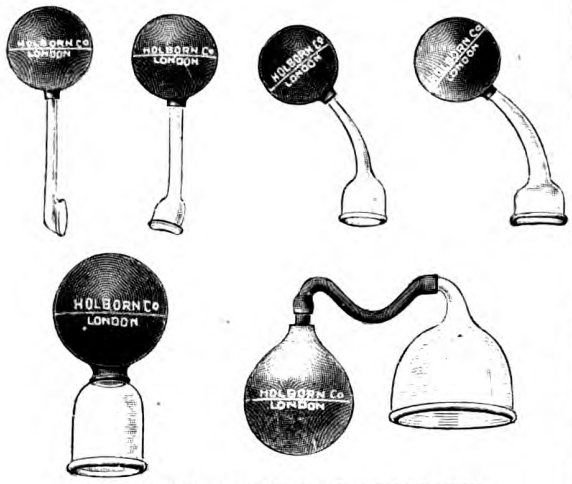
TENTH CONGRESS OF THE GERMAN ORTHOPÆDIC SURGERY SOCIETY.—The Tenth Congress of the Deutsche Gesellschaft für Orthopädische Chirurgie will take place as usual on the Tuesday of Easter week, April 18th, the day before the assembly of the German Surgical Society, in Langenbeckhaus, Ziegelstrasse, 10 and 11, Berlin. The hour for the opening of the Congress is 9 A.M. The President for 1911 is Dr. H. Hoeftman, Königsberg i. Pr.

# THE TREATMENT OF SKIN DISEASES BY HYPERÆMIA (BIER'S SYSTEM).

BY W. KNOWSLEY SIBLEY, M.A., M.D., B.C. CANTAB., M.R.C.P. LOND.,

HONORARY ELECTRO-THERAPEUTIST; ASSISTANT PHYSICIAN TO THE ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, LONDON.

I PUBLISHED in THE LANCET of August 29th, 1896, the first results obtained after two years' work on the hyperæmic treatment of rheumatic and other affections by the local application of dry hot air, and I have written several papers on the same subject since. This treatment, with various modifications, has now been adopted in most countries of the civilised world. Previously to the above time Professor Bier of Kiel had published some papers on a hyperæmic treatment which he produced by the application of compression bandages (*Stauungsbinde*), and which is now known as "Stauungs-hyperaemie," or obstructive hyperæmia. Of more recent date he, in conjunction with Professor Klapps, has devised a means of producing the same passive or venous congestion of quite local areas by a modification of the old cupping-glass method. With this object they have invented a series of easily adjustable exhaustion or suction glasses made of various shapes and sizes according to the part to be treated. These consist of a glass tube or cup, to one end of which a rubber ball is attached, and by varying the compression of the ball it is easy to produce a graduated degree of negative pressure, or partial vacuum, or exhaustion of the skin area to which the glass is applied. Larger apparatuses for treating more extended areas or for obtaining a more complete exhaustion are made with a detachable exhaustion pump, in place of the rubber ball.



Some suction cups used in the accompanying cases.

At the present time there are three methods for producing local hyperæmia—namely, (1) by the application of elastic bands or bandages; (2) by means of suction or cupping apparatus; and (3) by hot air. The first two agents produce a passive or venous hyperæmia, and the third an active or arterial hyperæmia. I have been trying some of Bier and Klapps's cups in the treatment of numerous forms of skin diseases and with results so satisfactory that I consider they are worth recording, in order that other workers in the field of dermatology may repeat and extend their use.

I suppose it must be admitted that the majority of skin diseases—in fact, perhaps nearly all, except those caused by parasites, either animal or vegetable—are the result of malnutrition of one or more of the complicated components which together form the epidermal covering of the human body. The general principle which underlies all scientific treatment of skin diseases—whether by external or internal remedies or by a conjunction of both—is to improve, by appropriate means, the nutrition of the affected superficial area. This is easily accomplished by producing an increased blood-supply to the part, and no simpler method is known than inducing this passive congestion or artificial hyperæmia by the scientific application of an exhaustion apparatus, giving rise to a partial vacuum.

In most of the cases treated, I have continued with the local application of the more or less routine ointments and lotions, both to the regions of the skin to which the cups have been applied, as well as to the other lesions—making a point especially of applying the local remedies soon after the hyperæmic treatment, and before the parts have returned to their previous condition. In this way it has been possible to compare the regions treated by hyperæmia in addition to those treated by ointments alone. I have also used this method in many cases in which I was treating some of the lesions with X rays. I have usually made a rule to treat all the lesions with the same ointments, and to begin with, only the eruptions on one side of the body with the suction cups, generally choosing the worst lesions for the new method.

The treatment has been given on the principle of applying exhanstion for various repeated periods of about five minutes' duration with three minutes intervals; usually two to five applications at each *séance*, but no sitting continued for more than an hour or repeated more than once a day. From the nature of the lesions the majority of the patients treated did not suffer any pain or even inconvenience. It was possible to produce a considerable amount of local congestion when desirable—that is to say, the treatment could be continued for longer periods, and with much greater amount of exhaustion of air in the apparatus than is possible or desirable when treating inflammatory lesions such as boils or abscesses. Nevertheless, the applications have to be made with intelligence and caution in order to produce the best results. In the majority of the hospital patients it has only been practical to treat them twice a week; in a few daily treatments have been administered.

I have so far used this treatment in the following classes of diseases, and with the results given under the separate headings, in which a few cases are briefly described to illustrate the chief features: acne, acne rosacea, alopecia areata, chilblain, eczema, keloid, lupus vulgaris, milium, scars, seborrhœa, sycosis, syphilis (tertiary), ulcers (chronic), urticaria (chronic and pigmentosa).

CASE 1. *Acne.*—A female, aged 24, had suffered from severe acne of the face for nine years. She had also some seborrhœa of the scalp. I prescribed a plaster mull of salicylic acid and creasote to be put on at night and a sulphur lotion afterwards to be applied. The right side of the face was subjected to the hyperæmic treatment, this being the more indurated of the two cheeks. After a month the right side was considerably softer and less indurated than the opposite one.

CASE 2. *Acne.*—A girl, aged 16. The rash appeared on her face five years ago; three years ago it had spread to her back, shoulders, and chest, being especially severe over the upper part of the breasts, with considerable general infiltration of the cheeks, forehead, and chin. After a fortnight's daily application of suction glasses, followed by rubbing in an ointment composed of sulphur and salicylic acid, all the areas treated were better than they had been for many months—in fact, parts of the face were cured of infiltration and almost freed from comedones.

CASE 3. *Acne.*—A youth, aged 19, had suffered for five years from severe acne all over the face and neck and considerable general infiltration of the skin. He was ordered a sulphur and salicylic acid ointment for all the diseased regions. I treated the right side of his face with X rays and the left with suction cups. After a few weeks' treatment both sides had considerably improved, especially the left, which had become less infiltrated, and the superficial tissues softer than those on the right side.

CASE 4. *Acne rosacea.*—A woman, aged 38, who had suffered for nine years from a very persistent eruption of the face, especially on the tip of the nose and the chin. The nose was always cold to the touch and very congested at the tip, and the chin was covered with groups of pustular acne, with general redness and infiltration of the surrounding tissues. She was ordered a salicylic acid paste, and after a very few applications of the cups to the nose and chin a very considerable improvement took place. For some time after each treatment the surface of the nose remained warm to the touch, and when last seen the condition was practically cured, but she continued herself to apply a small cup to any fresh spot which appeared and afterwards rubbed in the application.

CASE 5. *Alopecia areata.*—A man, aged 32. He stated that he lost all the hair of his head and face when he was 4 or 5 years old, and from this time he was quite bald till he was 14 years of age, when the hair of his head grew again, but not that of his eyebrows. For the last two years he had had some six patches of complete baldness on the vertex and occipital regions. He had been under treatment ever since, but with no improvement, and for some months had been applying lysol lotions of various strengths to the patches, together with various internal remedies, such as thyroid, &c. A suction cup was applied to the patch on top of the head, and after six weeks of daily treatments a fine growth of hair over the bare surface was visible, the other patches remaining as bald as ever. The skin of this region had lost the shiny appearance and looked altogether darker and more natural in colour.

CASE 6. *Alopecia areata and psoriasis.*—A woman, aged 37. She had a severe attack of rheumatic fever when she was 25 years of age, which left her much crippled for some months afterwards. She had suffered from psoriasis since childhood, always on the front of the knees, and at

times on the body and scalp, she never being entirely free from it. About six months ago she lost the hair from the nasal quarter of the left eyebrow, and a circular patch of complete baldness appeared in the centre of the outer half of the same eyebrow. She applied a small suction cup to the patch of baldness daily, and afterwards applied a weak lysol lotion, and in a few weeks several new hairs appeared on the patch, and at the time of writing it had more or less disappeared and is hardly recognisable except on close inspection. She also applied the hyperæmic method to some very persistent psoriasis spots over the knees, and then rubbed in a tar ointment, and she is now practically cured of the psoriasis.

CASE 7. *Keloid.*—A boy, aged 8, sent to me by Dr. G. Dawson. The child had fallen and cut his face on the pavement when he was five years old, and the resulting scar had gradually extended ever since and now measured 5·25 cm. by 4·50 cm. extending, involving, and everting the right lower eyelid, over the side of the cheek almost to the nose. The edges of the keloid were very hard, infiltrated, and much raised above the surrounding tissues. I treated the upper part of the growth with X rays, and the lower with suction cups, and came to the conclusion that the lower part became softer and improved more rapidly than the upper.

CASE 8. *Lupus vulgaris.*—A Jewess, aged 13, had a small spot on the tip of her nose, which was very red at the time and appeared after a severe cold three years ago. She attended at the London Hospital and afterwards for two years she had X rays applied at the Metropolitan Hospital, but the ulceration continued to spread. When first seen in July last the whole nose was covered by dry scabs covering an unhealthy ulcerated surface. She was ordered carbolic oil and a lanolin ointment. As soon as all the scabs had come away I touched parts of the ulcerated surface with solid $CO_2$, improvement soon showed itself, but the tip of the nose always remained cold. Bier's suction cups were afterwards applied, and in a short time the whole ulcerated surface had healed over. I gave her one application of the X rays during the treatment.

CASE 9. *Lupus vulgaris.*—A boy aged 5. This case was sent to me for treatment by Dr. A. Eddowes. Eighteen months previously the boy had an attack of measles, and a few weeks after this patches of lupus appeared in different parts of the body. The first came on the centre of the right cheek, then one on the left. Others shortly afterwards developed on the buttocks, thighs, elbow, wrist, and lastly on the chest. There were at this time 13 distinct lupus infiltrations which had not gone on to ulceration, but some were much raised from the surrounding skin and were threatening to break down. I treated the patches on the left cheek, elbow, and wrist with X rays, and those on the right cheek and leg and left buttock with suction cups. He was ordered a carbolic acid lotion and white precipitate ointment to apply to all the lesions. At the time of writing all the areas specially treated have considerably improved and some are nearly healed. Especially is this the case with the patch on the left buttock, where the lesion, which originally measured 2 cm. by 1·125 cm., is now only 1·25 cm. by 0·75 cm., the rest of the area being covered by a thin pale scar. The lesion on the right cheek measured 3·125 cm. by 2·25 cm., and is now 2·25 cm. by 1·80 cm., and the centre has healed. The one on the left cheek (which had been treated for eight weeks with X rays) had measured 3·5 cm. by 2 cm.; it is now 3 cm. by 1·75 cm., and there is no healing or scarring seen in the centre of this patch.

CASE 10. *Lupus vulgaris and scars.*—A woman, aged 27. She had suffered from a "red nose" for some years, and stated that the skin over it often cracked. Six months ago a pimple appeared on the left side of the tip of the nose, which soon became an ulcer, which had persisted in spite of all treatment. I am treating her with applications of a suction cup followed by X rays. Here, again, before treatment the tip of the nose is cold, but after a few minutes' hyperæmic treatment it becomes warm. She has also several scars under her chin and side of neck, the result of suppurating glands in childhood. There is one especially depressed scar under the centre of the chin, to which I am also applying the suction cups with gratifying results, the scar not being so depressed and disfiguring as before, and the ulceration of the tip of the nose has healed. This patient gave a positive von Pirquet's reaction.

CASE 11. *Milium.*—A girl, aged 6, with milia of cheeks and chin. Suction cups were applied to the areas of the lesions, and afterwards salicylic acid ointment was rubbed in. After a month's treatment all the milia had disappeared. It was noticed that at first the application of the exhaustion cups made the milia much more prominent for the time being, and so it was easy to see where to apply the ointment.

CASE 12. *Psoriasis.*—A woman, aged 35, who had had psoriasis for 16 years. She was in the hospital for three months 12 years ago, and it was nearly cured when she came out, but it never completely disappeared, and had been much worse lately. Recently it had been on her arms, legs, and abdomen. I selected some of the most indurated patches above the right knee-joint and over the patella and applied the cups. After treatment she rubbed in a compound tar ointment. The lesions treated by the hyperæmic method certainly reacted more satisfactorily than the others, and after a few weeks they had disappeared.

CASE 13. *Seborrhœa.*—A woman, aged 31, with seborrhœa of the scalp and a very persistent patch on the sternum and another between the shoulders. She also had some lichen planus on the right leg. I applied the cups to the patches on the sternum and between the shoulders, and she rubbed in some salicylic acid paste afterwards and in a few weeks they disappeared.

CASE 14. *Seborrhœic eczema.*—A woman, aged 59, who had been suffering for some months with a very irritable indurated eruption nearly all over the face, trunk, and limbs. The present attack began with a patch on the front of the right wrist, then one on the leg, and it had gradually spread over nearly the whole body. When first seen she had a considerable amount of induration of the face which gave her a leprous appearance, suggestive of an early case of mycosis fungoides. However, the face has very much improved. I have treated the worst lesions with X rays, and selected a few very indurated patches for the application of the suction cups, with very beneficial results. She has applied a paste consisting of salicylic acid (10 grains to the ounce) and most of the lesions have disappeared and the irritation has subsided.

CASE 15. *Chronic ulcer.*—A man, aged 56, who had suffered from varicose ulcers of the leg on and off for 30 years. At the time of beginning treatment he had a large ulcer, which he had had for six months, and a very indurated smaller one for 18 months. The larger one I treated with X rays, and the smaller one with suction cup. After the first applications a good deal of pus was drawn out, but later only clean serum exuded, and the ulcer healed up in a month.

*Summary.*

From my observations I have formed the opinion that practically all chronic forms of skin diseases are benefited by the hyperæmic treatment before applying local remedies. The action of ointments and lotions is considerably facilitated if a local congestion of the part is produced before they are applied. This local hyperæmia probably acts in two ways. In the first place, by producing a passive congestion, it increases the blood-supply, and so improves the nutrition of the part, and at the same time encourages the removal of deleterious products by the venous blood. In the second place, this local hyperæmia assists in the local action of the drugs when they are afterwards applied.

Of the cases so far treated, it would appear that the most satisfactory results have been obtained in psoriasis, especially in some very old-standing cases in which the lesions were very chronic and localised. We so often meet with cases of this complaint of many years' standing where some very persistent lesions are limited to a small area, such as the knees or elbows, and which resist all treatment. This is the class of case specially benefited by this method.

Some cases of lupus vulgaris have shown rapid improvement—in fact, from some recent observations the hyperæmic method showed earlier and much more satisfactory results than the X rays had done. Acne, both diffuse and local, reacted well, but these cases required a considerably greater amount of congestion and more frequently repeated treatments, both general to a large affected area, and afterwards local to the individual and more persistent comedones and pustules.

The immediate result of the local treatment is to produce a venous congestion of the skin, which increases the action of the sudoriferous glands, and gives rise to a varying degree of perspiration. This varies with the nature of the lesion and the degree of hyperæmia produced. In some conditions only an almost imperceptible amount of sweating results—perhaps just sufficient to produce a slight haziness on the sides of the cupping glass without a visible sweat on the skin. In others, such as many eczemas and seborrhœas, a profuse perspiration is quickly produced, and after a few minutes the whole part is bathed in sweat. In other cases the ordinary sweat is replaced by a serous exudation. In some instances of non-ulcerated lupus, which as a class perspire very freely under the treatment, a blood-stained serum exuded after a short time, and for this reason the cases require to be very carefully treated and only for very short periods at a time, one minute or so being usually sufficient.

I believe future research into the different reactions of various skin lesions under hyperæmia will be of considerable scientific value in assisting and defining the similarities or differences between some of the less easily distinguished skin diseases. These physiological or pathological reactions of various lesions may not only become a help to the pathologist but also of considerable aid to the diagnosis of some, at present, rather ill-defined and readily confused morbid states.

Duke-street, W.

# ON THE EXTERNAL APPLICATION OF MAGNESIUM SULPHATE IN THE TREATMENT OF ERYSIPELAS.[1]

BY KHAN BAHADUR N. H. CHOKSY, M.D. (HON. CAUSÂ) FREIBURG-I-BR., GERMANY,

SPECIAL ASSISTANT HEALTH OFFICER, BOMBAY MUNICIPALITY; IN CHARGE OF ARTHUR ROAD INFECTIOUS DISEASES AND MARATHA PLAGUE HOSPITALS, BOMBAY.

THAT the common and homely drug known as Epsom salts possessed any other property save the one usually associated with it was scarcely known up to within three years ago. The anæsthetic effects resulting from its subcutaneous application, however, induced Dr. Henry Tucker, of the Philadelphia General Hospital, to apply it for the relief of pain in local inflammatory conditions, with rather surprising results. For, apart from the relief of pain and discomfort, it was found that it controlled and eventually led to the cure of the inflammatory process. Numerous observations in gonorrhœal epididymitis and orchitis, gonorrhœal rheumatism, acute articular rheumatism, neuritis, &c., gave equally satisfactory results.[2] Erysipelas[3] and cellulitis were the other affections in which a marked beneficial influence was observed from its local application. And further, on account of its antispasmodic and analgesic properties, magnesium sulphate has been administered by intraspinal, subarachnoid, and subcutaneous injections for the relief of spasms in tetanus, as also of the lightning pains of locomotor ataxy. Miller[4] has reported 14 cases of tetanus so treated; 11 were treated with subarachnoid injections, and five of them recovered. The author says that magnesium sulphate brings about complete muscular relaxation. This prevents rapid exhaustion and enables the patient to take nourishment. The dose is 1 c.c. of a 25 per cent. sterile solution to each 25 lb. of the body weight of the patient. Paterson[5] reports a case of tetanus, in which he used 10 c.c. of a 10 per cent. solution subcutaneously—5 c.c. in each thigh—four-hourly. The injections were found to be painful, but the spasms were greatly relieved. He thinks that probably larger quantities of a weaker solution would obviate the local discomfort of these injections.

It may be interesting to note in this connexion that magnesium sulphate, when it fails through some cause or other to act as a purgative after internal administration, gives rise to serious toxic disturbances. In a case reported by Neale[6] it was observed that after taking an ounce of the salts no purging was produced, but there was stimulation of certain motor centres causing tetanic spasm of the face and arm, together with paralysis of the inhibitory fibres of the pneumogastric to the heart, paralysis of the muscular fibres of the stomach and bladder, and of the muscular coats of the blood-vessels, as shown by the absence of the radial pulse and general cyanosis.

In a further communication Dr. Tucker has described its effects in 19 cases of erysipelas complicated with alcoholism, acute nephritis, myocarditis, pneumonia, &c., with but three deaths, and in 35 uncomplicated cases without a single death. The latter recovered within two to seven days, pain and the usual local discomfort having been relieved in a few hours. No internal treatment was given. The treatment has been applied by him and others in nearly 700 cases of various forms of inflammation with uniformly good results, and he claims the following advantages for it in almost all cases:—

Firstly, the drug can be obtained at any country store, is easily made into solution, is inexpensive, non-toxic, and clean; it is also easy of application if the directions are properly followed.

Secondly, the patient promptly obtains relief from the distressing local symptoms usually present.

Thirdly, the temperature rapidly falls to normal usually during the second twenty-four hours, and does not rise again, thereby eliminating possible complications from fever.

Fourthly, internal medication is not indicated in uncomplicated cases, the only treatment being a milk diet for the first few days, or, to be more accurate, until the temperature reaches normal.

*Method of application.*—A saturated solution of magnesium sulphate in water (preferably strained through muslin) is to be applied round the limb or on the face as a mask, extending well beyond the inflamed area in 10–15 layers of gauze or a thin layer of absorbent cotton or lint, and covered with oiled-silk or wax-paper. The dressing should be wetted as frequently as it gets dry, about once in two hours. It should be removed once in 12 hours for inspection and immediately reapplied. The affected area should not be washed during treatment. Dr. Tucker says that the attendants complain of partial loss of sensation and tingling of the hands and arms lasting for some hours.

*Mode of action.*—No explanation is forthcoming as to how these effects are produced by magnesium sulphate. The editor of the *Therapeutic Gazette*, from personal experience and reports of other observers, whilst endorsing the utility of the treatment, that it certainly gives extraordinary results in the treatment of acute articular rheumatism, erysipelas, and the relief of pain associated with local inflammation, admits that the method, like several others in common use, is purely empirical, and that the local action of magnesium sulphate cannot be explained on any known experimental or other data. Nor is its osmotic influence adequate to explain these effects, as other salts having the same action do not bring about the same results. We must for the present at least be content with the empirical use of the method, leaving the explanation of its action to the future.

As erysipelas and cellulitis have been lately included among the infectious diseases that have to be received at the Arthur-road Hospital, I had occasion to give this method a fair trial in a limited number of cases. Erysipelas may be defined, in the words of a recent observer, as an acute inflammation of the epidermis due to the presence of one of the organisms of the streptococcus class, of which the streptococcus pyogenes is the most frequent example. Cellulitis is a strictly comparable inflammation of the cellular tissues, and when the inflammatory process involves both the epidermis and the cellular tissues the condition of cellulo-cutaneous erysipelas results. My observations extend to 72 cases only, seven of whom were moribund on admission and will therefore be excluded from consideration; 35 cases belonged to the cellulo-cutaneous type, several of them of long duration, with extension and deep suppuration and sloughing, especially of the upper and lower limbs. These cases, as was to be expected, did not respond well to the treatment. Of the remaining 30 cases, most of them were of erysipelas and a few of cellulitis. The solution of magnesium sulphate was applied according to the above directions, and it was found to have a marked effect in lessening the pain and in preventing further extension except in a very few cases of the severest type. No special internal medication was administered, except such as was necessitated by the complications present, such as pneumonia, exhaustion, cardiac weakness, &c. The improvement within a few hours after the application was extremely well marked in erysipelas of the face and head, with œdema in the eyelids, &c., the pain and swelling considerably lessening within one to three days with fall in temperature. In six cases, however, the inflammatory process was not controlled, and extended beyond the original area in spite of the treatment. A few illustrative cases will serve to demonstrate the action of the application.

CASE 1.—Erysipelas of the face and head; nose considerably swollen; duration four days. Immediate and steady improvement with fall in temperature from 103° F. to normal in two days. Discharged in 12 days.

CASE 2.—Post-operative erysipelas after mastoid operation; transferred from the Jamsetjee Jeejeebhoy Hospital on the fourth day of illness; extensive cellulo-cutaneous erysipelas invading the head, face, and neck. Much improvement in four days; subsequent extension downwards, involving the chest and back and both arms, with rise of temperature. Polyvalent antistreptococcus serum injected in addition: 280 c.c. in six injections, one each day (60 c.c., 60 c.c., 40 c.c., 60 c.c., 40 c.c., 20 c.c.). Rapid improvement thereafter. Convalescence tardy; discharged after seven weeks. The temperature chart shows remissions from 102° F. to 99° until the seventh day of illness, when the temperature came down to normal, rising again on the eleventh and fourteenth days to 101° and 102° respectively.

CASE 3.—Cellulo-cutaneous erysipelas involving both thighs and vulva; duration 15 days. Considerable relief with fall of temperature in four days; slight extension downwards, promptly controlled; discharged in three weeks. The chart shows that on the fourth day after admission the temperature came down to normal from 103·6° F. It rose again to 102° on the twentieth and twenty-second days of illness, and thereafter remained at the normal level.

CASE 4.—Cellulo-cutaneous erysipelas of face and neck; duration four days. Steady improvement and fall of temperature. After an interval

[5] THE LANCET, April 2nd, 1910.
[6] THE LANCET, August 15th, 1896.

of three days there was extension downwards to the chest, with elevation of temperature; compresses reapplied with good effect. Rapid convalescence; discharged in three weeks. The chart shows oscillations of temperature between 100° and 102° F. for six days corresponding to the extension of the disease to the chest.

The above four cases generally bear out all that has been claimed for this form of treatment. In almost every instance the immediate effects of the application of magnesium sulphate solution were extremely beneficial. Pain and swelling abated, fever decreased, and extension of the infection was controlled in the majority of cases. The results, however, have not been so uniformly good as Dr. Tucker's, inasmuch as advanced and neglected cases, as also cases of the graver type, so largely prevailed. In six cases, for example, the inflammatory process extended so rapidly, in spite of this treatment, that antistreptococcus serum had to be injected, but only one of them recovered. The quantity injected varied from 60 c.c. to 280 c.c. Excluding the above and the seven moribund cases there remained 59 cases with 13 deaths and 46 recoveries, equivalent to a case mortality rate of 22 per cent., as compared with 15·9 per cent. in Dr. Tucker's complicated cases.

On the whole, therefore, I can confidently recommend to notice and trial this extremely cheap and efficacious method of treatment of erysipelas and cellulitis.

# Clinical Notes:

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### NOTE ON A CASE OF SCLEREMA NEONATORUM.

BY R. E. SEDGWICK, M.D. CANTAB.,
HONORARY SURGEON TO THE CARLISLE DISPENSARY, ETC.

THE rarity of sclerema neonatorum justifies the publication of the clinical notes of every case, since the pathology of the condition has not yet been definitely settled.

The child was one of male twins and was 12 days old when my house surgeon, the late Dr. H. B. Stephenson, asked me to see the case with him. The twins had been healthy when born and weighed 5 lb. each. They were breast fed. The mother, aged 40 years, had had 14 children (including one previous twin-birth), of whom 11 were still living, the death of the three others being due to scarlet fever, bronchitis, and convulsions respectively. The conditions under which the family lived were poor and sordid. The child in question was noticed to be "queer" on the tenth day by the "nurse"—a neighbour—who drew attention to the peculiar stiffness of the left leg and thigh. When first seen, the child was wrapped up in blankets close to the fire. There was a tinge of jaundice in the skin and its cry was feeble and high-pitched. It had fed well and continued to do so. Both legs and both thighs were stiff and rigid, no movement of any sort being observed. The abdomen moved with respiration, but the hands and forearms were also rigid and motionless like the lower limbs. The skin of the affected limbs was normal in colour but cold to the touch, although circulation was well maintained as observable in the nails of the fingers and toes. The skin felt like soft leather, but the underlying tissues were very hard, almost bony. No impression could be made on the skin which could not be pinched up from the underlying tissues, and pressure did not vary the hardness of the muscles. Passive movement in the affected limbs was obtained with difficulty, giving an unpleasant impression of possible fracture. The funis was normal. There was a small hæmorrhagic effusion, the size of a sixpence, below the left internal malleolus and a smaller patch in the middle of the sole of the right foot. A blood count was made but with great difficulty owing to the extremely rapid coagulation. The blood was dark in colour and flowed very slowly. The result was as follows: Hæmoglobin, 100 per cent.; red cells, 4,300,000; white cells, 7800. A differential count showed a normal lymphocytosis.

The child died on the fourteenth day, and a very limited examination was allowed four hours after death. The skin was tough, parchment-like, and difficult to cut; there was no exudation on cutting through skin or muscle. In cutting the muscle a sensation was experienced as of drawing the knife through very stiff dough. All the muscle was very pale on section. No obvious abnormalities were noted. Pieces of skin, muscle, liver, and kidney were examined microscopically. The muscle shows a little segmentation and an occasional breaking up of the nucleus, but nothing else to comment upon. The other sections are practically those of normal tissue.

The muscle was sent to the Pathological Department of the University of Durham for analysis for fat. Professor R. A. Bolam reported as follows:—Muscle from thigh: weight of muscle, 0·16 gramme; weight of fat, 0·135 gramme; fat percentage, 84. Muscle from abdomen: weight of muscle, 0·395 gramme; weight of fat, 0·16 gramme; fat percentage, 40·5. Average fat percentage of normal muscle, 2·27.

The above facts would appear to show that sclerema neonatorum is not at any rate an inflammatory condition, while the extraordinary fat percentage in the muscle seems to point to a rapid chemical change which, however, does not appear to have much effect upon muscle structure.

Carlisle.

### NOTE ON A CASE OF SLIDING HERNIA OF THE SMALL INTESTINE.

BY GWYNNE WILLIAMS, M.S. LOND., F.R.C.S. ENG.,
SURGICAL REGISTRAR, UNIVERSITY COLLEGE HOSPITAL, LONDON.

THE patient, a negro, aged 25 years, was admitted to the Seamen's Hospital, Greenwich, for the cure of a right inguinal hernia. On dissecting away the coverings of the cord, what was taken to be the sac was separated out and opened, but was found to be only a serous-lined cavity which had no communication with the sac of the hernia. This latter was situated external to it and attached to it by a fibrous cord. The sac of the hernia could be made more prominent by pulling it down, and could be reduced entirely into the abdominal cavity. It contained something which felt like bowel, but it was impossible to reduce the contents without reducing the sac itself, thus showing that the bowel must be adherent to the sac wall. The hernia was of the oblique variety, the deep epigastric artery running along the inner side of the neck.

On opening the sac there was seen to be a coil of bowel adherent to the wall and a coil apparently of small intestine, but this coil had no mesentery, being only surrounded by peritoneum on three sides. On tracing it towards the middle line a mesentery gradually appeared, while in the opposite direction it remained in the same condition as in the sac until it ended in the cæcum. This, as far as could be made out through the limited opening in the abdominal wall, also had no mesentery. The portion of the ileum without a mesentery was about six inches in length and was bound down to the parietal peritoneum of the iliac fossa which had been dragged down into the hernial sac. There were no other adhesions present, the appendix was quite free, the peritoneum was perfectly smooth—in fact, there was nothing to suggest that the condition was the result of inflammation, and one must conclude that it was a congenital abnormality. The intestine being fixed to the iliac fossa, the coil in the sac was adherent posteriorly. The upper part of the sac was cut away and the upper cut edge of peritoneum stitched to the peritoneum reflected from inferior aspect of the ileum. The canal was closed by Bassini's method.

I cannot find any account of this condition either from the surgical or from the anatomical aspect.

New Cavendish-street, W.

### NOTE ON A CASE OF SUPPURATIVE PYLEPHLEBITIS.

BY G. A. BROGDEN, B.A. CANTAB., M.D., CH.B. EDIN.

THE following case may be of interest since it records an instance of recovery from acute suppurative pylephlebitis.

The patient, a boy, 12 years of age, was under my care suffering from an attack of appendicitis. During convalescence and after the temperature had been normal for several days it ran up to 103° F., he had a rigor, and complained of pain, which was localised in the epigastric region. A smooth, well-defined swelling, very sensitive to pressure, became palpable in this region. A diagnosis of acute suppurative

pylephlebitis was made, and a surgeon who was called in suggested an operation as a last resource. I was present at the operation, and the following is an extract from notes made at the time. The liver was exposed by a mesial incision in the epigastric region. The right lobe appeared normal, but the left lobe was very swollen and intensely congested. There was no peritonitis. A trocar and cannula were introduced deeply into the liver substance, and a small quantity of very fœtid pus escaped. The opening thus made was slightly enlarged, a half inch drainage-tube was inserted, and the abdominal wound was closed. The patient remained very ill for three days; then the temperature began to fall, and he made an uninterrupted recovery. A little pus escaped from the wound for about a week. The tube was removed altogether at the end of a fortnight. The condition of the appendix was not ascertained.

Oadby, Leicester.

### MEDICAL SECTION.

*Loss of Abdominal Movements in Pericarditis.*

A MEETING of this section was held on Jan. 24th, Dr. J. MITCHELL BRUCE, the President, being in the chair.

Dr. A. E. GARROD read a paper on the Auscultation of Joints, which was published in THE LANCET of Jan. 28th, p. 213.

Dr. W. ESSEX WYNTER read a paper on Absence of Abdominal Respiratory Movement as an Indication of Pericarditis. He said that in a disorder so serious and attended with so little obvious indication as pericarditis, an additional and manifest physical sign, provided it was to be trusted, should be especially welcome. The sign suggested in this communication was inhibition of the action of the diaphragm, indicated by suppression of normal abdominal respiratory movement, and had probably been hitherto overlooked through examination being unduly restricted to the chest in such cases. Loss of abdominal respiratory movement as an indication of disease, except in paralysis of the phrenic nerves, had been to a great extent monopolised by observers in connexion with peritonitis and acute abdominal lesions. It was largely from that standpoint that Dr. William Pasteur dealt with that phenomenon and the resulting thoracic lesions in his highly instructive Bradshaw lecture. Primary thoracic disease, however, had its share in causing suspended function of the diaphragm, though in the majority of instances affecting the lung and pleura that was one-sided, and the influence on abdominal movement consequently less marked. In acute pericarditis, on the other hand, the cessation of phrenic action was bilateral, and consequently absence of abdominal movement was as obvious as in abdominal disorders, albeit other abdominal manifestations, such as muscular rigidity and general tenderness, were lacking. There was no doubt that when attention was directed to the matter and a definite note made as to the presence or absence of abdominal movement, that feature would be found fairly constant in acute pericarditis, especially that with fibrinous exudate. When the front of the body was fully exposed the stillness of the abdomen was very striking, suggesting peritonitis, unless, as sometimes happened, there was inspiratory recession, which might mislead, unless the want of correspondence with the movement of the upper chest was noticed. The inertness of the diaphragm was not merely inferred, but by X ray screen examination could be actually observed, the midriff mounting high into the thorax and exhibiting no contraction, and in some instances an actual rising of a quarter of an inch with each inspiration. In one case the contents of the upper abdomen, such as the kidneys and opaque masses in the intestine, could be seen to participate in that upward inspiratory movement. Concomitant and indeed consequent phenomena were: a tendency to dilatation of the hollow abdominal organs, especially the stomach, collapse and loss of function in the lower lobes of the lungs, slight upward displacement of the heart and of the organs beneath and in contact with the diaphragm. Loss of abdominal movement, as a sign of pericarditis, was the more valuable in that it might precede and outlast the other indications and so afford grounds for anticipatory or retrospective diagnosis. The condition afforded a reasonable explanation of the cyanosis and dyspnœa so usual in the complaint and of the upright position so commonly assumed by the patient. The former expressed the effect of respiration restricted to the function of the upper lobes of the lungs, and the latter pointed to an unconscious effort on the part of the patient to utilise the weight of the abdominal viscera to depress the passive diaphragm and enlarge the thoracic area. Restriction of abdominal movement was apparently more marked in fibrinous than in effusive pericarditis, movements being more productive of local irritation in the former than in the latter condition, as was the case in other serous sacs, such as the pleura and peritoneum. Incidentally the observation of the existence of a limited amount of serum in at least one of the cases by X rays, in the absence of other clinical indications, was suggestive that extended observations might show that to be more frequent than was formerly supposed, for in the recumbent posture a few ounces of fluid would naturally gravitate to the lowest part of the sac, and scarcely reveal its presence over the front of the heart.

Dr. PERCY KIDD said that he had a strong conviction that he had seen a motionless abdomen in cases of pericarditis.

Dr. M. A. CASSIDY said he had seen two cases diagnosed as suffering from acute abdominal lesions which turned out to be instances of pericarditis.

Dr. NATHAN RAW said that after receiving the notice of the paper on the diary card sent out by the society he had seen a case of acute pericarditis in which the abdomen was quite fixed, the recti muscles being quite tense.

Dr. R. HUTCHISON said that the loss of movement did not occur in all cases of pericarditis. Perhaps the loss of movement was noticed when the pericardial diaphragmatic surface was affected.

Dr. A. F. VOELCKER said he followed Dr. Hutchison in what he had said about the absence of movement of the abdomen in pericarditis.

Dr. JOHN FAWCETT thought they should be cautious in drawing conclusions in the early stages of cases, because some of these cases were suffering from pneumococcal peritonitis in which the pericarditis was only a sign of a further infection.

The PRESIDENT said that there were genuine abdominal cases from which some spread of inflammatory abdominal process might take place through the diaphragm into the pericardium.

Sir JOHN BROADBENT drew attention to the fact that he had seen a pericardial case in which on a deep inspiration some abdominal movement took place in the lower part of the abdomen.

Dr. ESSEX WYNTER concluded his reply by saying that he was not prepared to say that every case of pericarditis would show loss of movement in the abdomen.

### OTOLOGICAL SECTION.

*Bacteriology of Chronic Post-nasal Catarrh.—Exhibition of Cases.*

A meeting of this section was held on Jan. 20th, Mr. ARTHUR H. CHEATLE, the President, being in the chair.

Mr. C. E. WEST read a paper entitled "The Bacteriology of Chronic Post-nasal Catarrh—a Preliminary Study from 50 Cases." He said that the material for examination was obtained by means of a specially devised post-nasal cannula shielding a sterile swab, which could be made to protrude when the cannula was in the naso-pharynx and could be withdrawn into its sheath before the instrument was removed from the mouth. Pneumococci were found in nearly 70 per cent. and were predominant in 36 per cent. of the cases. Streptococci (undifferentiated) were isolated in 24 per cent. Staphylococcus aureus occurred, generally with pneumococci and streptococci, in 26 per cent. Friedländer's bacillus was found in 12 per cent., being predominant in 6 per cent. Micrococcus catarrhalis appeared in 10 per cent. After contrasting these with control cases Mr. West concluded that the flora did not appear to differ materially in kind from that found in the average naso-pharynx. He hoped by further researches to furnish data on which broader deductions could be based.

Dr. W. MILLIGAN described two cases of Otitic Cerebellar

Abscess, which recovered after operation, and two cases illustrating the surgery of labyrinthine infection.

The PRESIDENT showed a patient with an Exostosis in the Tympanic Cavity, and in conjunction with Mr. G. J. JENKINS described a unique case of great importance in which disease in a large sinus tympani caused persistence of discharge after the radical operation. Caloric tests were applied by a copper conductor and ethyl chloride spray to the exposed inferior crus of the posterior semicircular canal.

Mr. CHICHELE NOURSE presented a boy who had recovered from a localised Infection of the Lateral Sinus without ligature of the jugular vein.

Dr. G. C. CATHCART described the application of Bier's treatment in a case of Acute Suppurative Otitis Media with signs of Mastoiditis.

Dr. DAN MCKENZIE demonstrated Barany's Lärm Apparat upon a man with apparently absolute unilateral deafness due to a cause unknown.

## OPHTHALMOLOGICAL SOCIETY.

*The Pituitary Body and Lesions of the Optic Chiasma.—Exhibition of Cases and Specimens.*

A MEETING of this society was held on Jan. 26th, Mr. G. A. BERRY, the President, being in the chair.

Mr. J. HERBERT FISHER read a paper entitled "The Pituitary Body and Lesions of the Optic Chiasma." After alluding to cases which from time to time had been reported in the Transactions of the society, Mr. Fisher dealt shortly with the development, structural anatomy, and function of the hypophysis cerebri. Reference was made to the recognition and elucidation of acromegaly by Marie in 1886 and subsequent years, and Frohlich's train of symptoms known as "dystrophia adiposo-genitalis" was sketched. Recent experimental work on the pituitary body and its function by Pavlesco and Harvey Cushing was narrated. The association between the hypophysis cerebri and other ductless glands was reviewed. Cushing deduced from his extensive work on the subject that acromegaly and gigantism were the result of hypersecretion of the anterior lobe of the pituitary gland, while Frohlich's train of symptoms was the result of hyposecretion. Mixed cases were explained on this theory. Mr. Fisher then detailed nine cases of pituitary body and chiasma lesion which he had personally observed, over a long period of time in most instances. The cases provided examples of acromegaly and of Frohlich's syndrome in complete and in partial manifestation; one complete case showed that this train of symptoms might develop in the adult as well as in the child. The cases showed the early liability to sexual disturbance and impotence in pituitary body lesions. Primary atrophy, not papillœdema, was the ophthalmoscopic phenomenon in all the cases. Some examples of very practical benefit by treatment with thyroid extract or pituitary extract were afforded. In the later cases special extract of the anterior pituitary lobe only was being tried with some encouraging signs of benefit. In every case charts of the field of vision were exhibited and the necessity of perimetry for the diagnosis was insisted on. The additional value of X rays in demonstrating enlargement and destruction of the sella turcica was well examplified by the skiagrams of the patients.—The PRESIDENT, in initiating the discussion on the paper, invited members to narrate any experiences they might have had of such cases, and particularly if they had had any in which treatment had been beneficial; there were probably many who had seen cases of bi-temporal hemianopia due to acromegaly. An interesting point was as to the proportion of cases of acromegaly in which eye symptoms were present. Did the cases showing bi-temporal hemianopia begin with changes in the pituitary body, or were they cases in which, owing to changes subsequently taking place in the sella turcica, there were pressure effects on the decussating fibres which ran to the ventral surface of the chiasma?—Mr. J. B. LAWFORD reported a case very similar to those of Mr. Fisher. The patient was a man aged 36 years, and was under observation 21 months. He came with his left eye nearly blind, there having been a history of progressive loss of sight on that side. The vision in the right eye at that time was 6/12. He was a thin man, but healthy-looking, and the loss of sight was his only complaint. There was no definite history of syphilis, although he had a sore on the penis seven years previously, but without secondary symptoms. The other special senses were normal; there was no headache, no sexual incapacity, and no signs of tabes. There was optic atrophy well marked in the left eye, and pallor of the right disc. On account of the history of a chancre, he was put on antisyphilitic treatment for a short time, but no improvement occurred, and three months later he had thyroid treatment. At that date the vision in the good eye had been reduced from 6/12 to 6/24 and 18 J., and he had lost a large part of the temporal field in the right eye. After treatment by thyroid, the central vision rose from 6/24 to 6/6, and from 18 J. to 1 J. X ray examination of the base of the skull was negative. Later there was again failure of sight, and he was again taken into hospital and put on to pituitary extract alternating with thyroid extract; Mr. Lawford did not then know of the special anterior lobe extract. The vision steadily failed, and when last seen that of the right eye had fallen to perception of hand movements. The man remained free from other symptoms of disease.—Mr. R. W. DOYNE expressed regret that Mr. Fisher did not ascertain the field for colour in those cases. In some cases showing hemianopic loss there was a normal white field. Ten or 12 years ago he published particulars of one case of acromegaly in which the field for white light was normal, but the whole of the upper sector was lost for colour. In that case, which went from bad to worse, he could tell beforehand how it was going by the loss of colour which occurred first.—Mr. J. JAMESON EVANS (Birmingham) narrated the case of a patient who suffered from hemianopia but no other change. That went on for ten years, and then he developed some other symptoms, which led to an operation for pituitary growth, but it was not successful. He thought that in some of the cases cryptorchism was present. He treated one case with thyroid extract, with loss of weight as a consequence. Pituitary extract resulted only in an increased secretion of urine. Cases of acromegaly seemed to do well on mixed treatment by thyroid extract and pituitary extract.—Mr. F. RICHARDSON CROSS said the cases seen were those in which there was pressure on the chiasma. He had a young woman in whom the menstrual function was very imperfect, and whose mental attitude was unsatisfactory. He operated on her for squint, and she had typical symptoms of acromegaly. She had been treated unsuccessfully with thyroid extract and pituitary extract, and he showed charts of the fields of vision. He also showed some charts of a patient who had pressure on the chiasma, but in whom there was no acromegaly.—Mr. F. HEWKLEY asked whether there was hyperæsthesia of the remaining sentient portion of the retina. In one case when the person passed by a street lamp in a suburb the light would apparently be very dazzling to his eyes.—Mr. FISHER replied that the cases which he had reported were not acromegalic, with the exception of the first one. He felt sure that in many instances there was enlargement or growth in the region of, if not developing in, the pituitary body and pressing on the chiasma. He regretted he did not investigate the colour fields, owing to the stress of out-patient work. But he would hesitate to accept Mr. Doyne's observations that early contraction or loss of the temporal portion of the field for colour must be an inevitable precursor of loss of vision, though if that were so it would be a great guide to prognosis.

Mr. E. A. DORRELL showed a drawing of Unusual Appearance of the Iris in Congenital Syphilis; also a Paracentesis Needle for use in preparing vaccines from the aqueous.

Mr. R R. JAMES exhibited a case of Pedunculated Tumour of the Conjunctiva.

Mr. ANGUS MCNAB showed a case of False Projection.

Mr. J. S. HOSFORD brought forward six cases illustrating Congenital Dislocation of the Lens.

## NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

*Exhibition of Specimens.—Cæsarean Section under Spinal (Stovaine) Anæsthesia.—Double Ovarian "Cold" Abscess.—Manipulation Lacerations of Uterus.*

A MEETING of this society was held on Jan. 20th, Dr. W. K. WALLS, the President, being in the chair.

Dr. H. BRIGGS showed specimens of (1) Tubal Pregnancy with Thin-walled Cyst of the Opposite Side of the Pelvis;

(2) Old Hydatid Cyst with 15 Years' History; and (3) Placental Tissue in the Uterus in Two Cases without the Usual Clinical History.

Dr. A. DONALD showed Tubercular Ovaries, Tubes, and Uterus which had been removed from a girl aged 18 years. The symptoms were mainly continuous uterine hæmorrhage for three months with pelvic discomfort. There was some loss of flesh but not very marked. Examination revealed a tense swelling in the pouch of Douglas continuous with a tender mass in the right iliac region. On opening the abdomen on July 27th, 1910, two ovarian abscesses were found firmly united to one another, to the uterus, and to surrounding structures. The adhesions were so dense that the only way of removing the tumours was to work from one side of the pelvis to the other, removing the left appendages, uterus, and right appendages in one mass. The patient made a good recovery and at the present time (six months after the operation) was in good health. The pathological examination by Dr. Fletcher Shaw showed the presence of giant cells and small-celled infiltration in both tubes, in a large lymphatic gland attached to the mass, and in the endometrium.

Dr. J. B. HELLIER showed a specimen of Dermoid Cyst of the Right Ovary, Simple Cyst of the Left Broad Ligament, and Bilateral Papillomatous Ovarian Disease.

The PRESIDENT reported a case of Cæsarean Section under Spinal (Stovaine) Anæsthesia, mitral stenosis and kidney disease rendering the patient a bad subject for general anæsthesia. The operation was performed when the patient was about eight months pregnant, as there was great dyspnœa, accompanied by marked water-logging of the lungs, general œdema, and a large amount of albumin in the urine. The patient made a good recovery and her general condition was greatly relieved. Unfortunately the baby died in a convulsion when three days old.

Dr. WILLIAM FLETCHER SHAW showed a case of apparently Double Ovarian Abscess which occurred in a patient without any rise of temperature or pulse or general malaise. The walls of the abscess cavity were hyperæmic but showed no granulation tissue. The contents were chiefly colloid material with a good number of leucocytes; no micro-organisms were found. He raised the question whether these apparent abscesses without general symptoms were really due to micro-organismal infection or were simple cysts which had rapidly enlarged, their contents merely assuming the appearance of pus.

Dr. A. J. WALLACE related two cases in which Manipulations carried out to effect delivery had produced serious Lacerations of the Parturient Uterus. A primipara, aged 31 years, was sent into the maternity hospital with the history that labour had begun 48 hours previously. The midwife summoned medical assistance and then attempts were made to deliver first with forceps, then by version. It was thought that a tough fibrous band divided the uterus into two halves and that this prevented delivery. The patient was suffering from profound shock; her pulse was 140, and there was some vaginal bleeding. A deep tear was found in the posterior vaginal wall, the cervix was badly lacerated, and the anterior aspect of the retraction zone was torn away from its attachments, the retraction ring forming the band described. A leg was brought down and delivery effected, but the patient's condition did not warrant further interference, apart from her being "suspect" as regards infection. Death occurred three days later from sepsis. The second case was that of a woman, aged 40 years, who had had five children. At the onset of labour a breech presentation was converted into a vertex by external version. Inertia uteri was present throughout, necessitating manual dilatation of the cervix and the use of forceps. On recovering from the anæsthetic the patient complained of agonising abdominal pain, tympanites developed and increased, neither fæces nor flatus being passed, whilst the pulse-rate remained at 120. Dr. Wallace saw her 48 hours later; the vaginal portion of the cervix was intact, but a tear through the lower uterine segment opened into the left broad ligament, the lamellæ of which were widely separated by blood and clot. Through the posterior lamella there was a rent leading into the peritoneal cavity. When the abdomen was opened much blood and clot escaped. Abdominal hysterectomy was performed, and the patient recovered after a stormy convalescence.

# LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

*Intussusception—Red Degeneration of Fibroids in Pregnancy.—Exhibition of Cases, Specimens, &c.*

A MEETING of this society was held on Jan. 20th, Dr. A. CHRISTY WILSON, the President, being in the chair.

Mr. H. J. ROPER read the notes of a case of Intussusception in a child aged 8 years. The symptoms, pain and vomiting, had lasted for nine hours. On opening the abdomen he found it quite impossible to reduce the invagination, which was of the ileo-colic variety, on account, as he thought, of it having passed through the ileo-cæcal valve. The intussusception was almost eight inches long, and fearing the consequences of resection, he made a lateral anastomosis between the ileum above the intussusception and the colon beyond the point to which it extended, leaving the intussusception *in situ*. The child recovered and has remained well ever since (November, 1909). He was of opinion that this operation should be performed in recent cases where the condition of the invaginated gut was good, in preference to resection which was notoriously fatal.

Mr. C. H. GREENWOOD made remarks on a Case of Red Degeneration of Fibroids in Pregnancy, with acute symptoms, in which hysterectomy had been performed. The patient, a primigravida, was seized with sudden acute pain and vomiting; a diagnosis of ovarian tumour with twisted pedicle was made. The condition found at operation was red degeneration of a pedunculated fibroid; as there were several other fibroids, hysterectomy was done. Recovery was uneventful. The specimens showed early red degeneration in streaks and patches amid normal myoma tissue. The red areas showed degenerate muscle fibres, blood stasis, and dilated vessels, but no thrombosis. The pale areas showed no vascular dilatation. It was suggested that the degenerating myoma cells liberated some bodies which act first as hæmolysins, thus causing the discolouration, and secondly, as fibrin-ferments, leading to stasis (as seen in the present specimens) and then thrombosis; and that the onset of the acute symptoms corresponded to these changes. The thrombosis, &c., was thus secondary to the degeneration, not the cause of it.

Dr. E. F. TREVELYAN showed: 1. A case of Muscular Dystrophy (Pseudo-hypertrophic Paralysis) of 12 years' duration in a man now aged 20 years. There was pseudo-hypertrophy of the calf muscles, but particularly of the triceps muscles. There was marked atrophy of the glutei and latissimus dorsi, but only slight atrophy of the lower pectorals and spinati. The scapulæ were slightly winged. The gait was waddling and there was lordosis in the lumbar region. 2. A case of Graves's Disease undergoing retrogression in a woman, aged 40 years. She had been long under observation and had an acute attack of insanity about ten years ago. All the signs had considerably improved, but somewhat unsymmetrically. Thus the exophthalmos had almost disappeared on the left side and the tremor was less marked in the left than in the right arm.

Mr. H. COLLINSON showed a case of Calculous Anuria in which, after an attack of pain in the left kidney region, followed by hæmaturia, complete suppression of urine occurred, and lasted for five days. Examination by the X rays showed no evidence of calculus. Exploration of the left kidney on the fifth day of anuria revealed a calculus impacted in the opening of the ureter. This was extracted through an incision in the renal cortex and the kidney was drained. Urine began to be secreted in a few hours. Recovery was uneventful.—Dr. L. A. ROWDEN explained that the calculus on analysis was found to be almost pure uric acid stone, and hence was not demonstrable by the X rays.

Mr. S. THOMPSON ROWLING showed an Improved Apparatus for Administering the Oxygenated and Warmed Vapours of Ether and Chloroform for General Anæsthesia. The apparatus consisted of two cylindrical glass tubes placed vertically side by side, the one containing ether, the other chloroform. Warmed oxygen was passed through the ether or chloroform, and the oxygenated anæsthetic vapours were administered to the patient through a perforated tube arranged in a wire frame, which was covered with gauze. The cylindrical glass tubes were supported and the oxygen was warmed by a water-jacket, arranged to serve the additional purpose of

forming an efficient protection for the glass. Any proportion of oxygenated ether or chloroform, either alone or together, could be administered, or pure oxygen alone if desired. The administration is on the plenum principle; the presence of oxygen causes very quiet respiration and a good pulse, and a profound narcosis can be maintained with safety; there are also no blueness and no mucus.

Mr. J. F. DOBSON showed a specimen from a patient upon whom anterior gastro-enterostomy and entero-enterostomy for a large Saddle Ulcer on the Lesser Curvature of the Stomach had been performed seven months previously. The patient gained 2 stones in weight and was free from pain for a month after the operation. She then began to complain of severe pain after food. Eventually the obdomen was reopened and a perforating ulcer adherent to the abdominal wall was found in the jejunum just below the gastro-enterostomy opening. The gastric ulcer had healed, leaving a scar which produced a marked hour-glass contraction of the stomach. The greater part of the stomach was excised (including the gastro-enterostomy opening and the scar of the ulcer), and the efferent and afferent loops of bowel. The continuity of the stomach and small intestine was restored, the patient making a good recovery.

Dr. C. OLDFIELD showed a series of specimens to illustrate the advantages of removing the body of the uterus, together with the appendages, in cases where the latter had to be removed for gross disease. The specimens were: two of Double Pyosalpinx, two of Bilateral Tuberculous Salpingo-oöphoritis, one of Malignant Disease of the Ovary with Dual Primary Growth in the Uterus, and one of Bilateral Ovarian Cyst. The immediate and remote results were better than when the uterus was left, and this fact was now becoming generally recognised by gynæcological surgeons.

Mr. J. STEWART showed three cases treated by "606." 1. A male, aged 34 years. Intense headaches, Jacksonian epilepsy of the right side of the face, ten days later paresis of right arm and hand. Retention of the urine ensued on three occasions; optic neuritis. Potassium iodide was of no effect. "606" was administered three weeks ago. The patient was slowly but perceptibly improving. 2. Ulceration of the right side of the face and anterior triangle of the neck with fistula of Stenson's duct of three years' duration, during which time the patient was on antisyphilitic remedies. "606" was given 27 days ago, and the ulceration had almost healed. The fistula was not closed. 3. Inveterate ulceration of the tongue, throat, lips, and cheek, which had resisted mercury, potassium iodide, arsenic, and Littmann's decoction. The ulceration cleared up in three days.

Dr. BEDFORD PIERCE showed, with skiagrams, a Lead Pencil removed from the Duodenum by Mr. H. Littlewood.

Dr. A. BRONNER showed several instruments for the Suction Treatment of various diseases of the ear and nose. By this method in cases of acute purulent affections of the the middle ear or accessory nasal cavities the pus could be removed, the swollen membrane reduced, and drainage of the cavities improved. In some cases of otosclerosis the hearing was improved and the tinnitus lessened.

Cases and specimens were also shown by Dr. A. G. BARRS, Mr. R. LAWFORD KNAGGS, Mr. G. CONSTABLE HAYES, Dr. T. WARDROP GRIFFITH, Mr. B. G. A. MOYNIHAN, Dr. M. COPLANS, Mr. MICHAEL A. TEALE, and Dr. W. H. MAXWELL TELLING.

## MEDICAL SOCIETY OF LIVERPOOL.

*Election of Office Bearers and Members of Council.*

AT the annual meeting of this society held on Jan. 19th the following list of office-bearers and members of council was adopted:—President: Dr. T. R. Bradshaw. Vice-presidents: Dr. J. E. McDougall, Mr. G. P. Newbolt, Dr. C. S. Sherrington, and Dr. W. B. Paterson. Treasurer: Dr. J. Lloyd Roberts. General secretary: Dr. Thomas Bushby. Secretary of ordinary meetings: Dr. W. B. Warrington. Secretary of pathological meetings: Dr. Ernest E. Glynn. Librarian: Dr. J. C. M. Given. Editor of the Journal: Dr. John Hay. Council: Dr. T. H. Bickerton, Dr. Richard Humphreys, Dr. Herbert R. Hurter, Mr. T. C. Litler Jones, Dr. John Owen, Dr. Joseph Unsworth, Dr. R. W. MacKenna, Mr. C. V. Vereker, Dr. Owen T. Williams, Dr. Robert E. Kelly, Mr. Arthur J. Evans, and Mr. J. E. O'Sullivan. Auditors: Mr. T. C. Litler Jones and Dr. Stanley A. Gill.

*Tumours of the Adrenal Glands.—Methods of Localisation of Foreign Bodies by the X Rays.*

A meeting was held on Jan. 28th, Dr. J. E. MCDOUGALL, Vice-President, being in the chair.

Mr. R. C. DUN and Dr. ERNEST E. GLYNN communicated a paper on Tumours of the Adrenal Glands, with especial reference to those occurring in children. Mr. Dun first described the features of a case in which the patient was a girl, aged 5 years, of precocious development. The body was covered largely with fat, and hair was copious in several parts—viz., over the scalp, the pubis, and in the axillæ. A large tumour was present in the right flank having the characteristics of a renal tumour. The child died in a few days from bronchopneumonia. A complete post-mortem examination was made by Dr. Glynn, which showed that the tumour was certainly one of the adrenal body; the kidney was found to be free, but was embedded on the under surface of the tumour. Mr Dun and Dr. Glynn then considered the previous 16 cases already published and compared their own case with them. They gave the following classification:—*Group A* (from cortex).—Malignant hypernephroma associated with great precocity in children of both sexes or great muscular development with true sexual precocity in males. *Group B* (? from cortex or medulla).—Round-celled sarcoma: (1) Hutchinson's type with metastases in the skull; and (2) Pepper's congenital type with tumours in the liver. *Group C*, unclassified. Primary tumours in adults were, they said, less easy to classify, but malignant hypernephroma in the adult female might produce secondary male characteristics. Precocity in children was sometimes associated with tumours in other glands.—Dr. W. BLAIR BELL said that it was important to remember the inter-relation of the various ductless glands. The secretions of the ovary and thyroid were antagonistic to those elaborated by the infundibular portion of the pituitary and the medulla of the adrenals. This was shown by the effect upon blood pressure and upon the calcium metabolism. He asked how far variation in function was accompanied by change in structure of the gland itself or how far structural change was really due to alteration in the activity of some other of the glands? Hence, instead of removing a hypothetically over-active ovary in osteomalacia, as had been done in the past, adrenalin was now given with success to antagonise the over-active ovary. Perhaps infundibular extract would have the same effect. He pointed out that in some cases, as in that just related, it was only the secondary characteristics of puberty that were developed; in others there was actual precocious sexual activity. He thought that in the latter cases there was a coincident reaction in the specific genital glands. He had long urged that the specific glands were not alone responsible for the genital activity, but that many of the ductless glands participated in the process. They had now evidence that this was so.

Dr. W. C. ORAM read a paper on the Methods of Localisation of Foreign Bodies by the X Rays. A radiogram was shown of a needle two inches in length completely embedded in the tongue of a child aged 4 years. Diagrams were exhibited illustrating the process of localising a bullet in the hip by a screen examination. Various methods of localising a needle in the hand were described and their accuracy and limitations discussed, and a process described by which when two stereoscopic negatives were used, together with a prepared curve connecting the shift of the shadow of the needle with its depth in the tissues, the distance of the needle from the surface could be estimated to the tenth of an inch.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

*Cases Illustrating the Operation of Pubiotomy (with Skiagrams).—Treatment of Eclampsia.*

A MEETING of this section was held on Jan. 6th, Dr. HENRY JELLETT, the President, being in the chair.

Dr. E. HASTINGS TWEEDY exhibited six of nine cases of Pubiotomy. The three patients not shown differed in no way from those present. The most recent operation had

been performed eight weeks previously, while four years had elapsed since the first. All the patients walked without discomfort or limping and had made uneventful recoveries.—The PRESIDENT said that he had performed the operation at the Rotunda Hospital without having seen it done, and had found it so easy that others should find no difficulty. Mr. Hayes's skiagrams showed clearly the conditions of the bones.—Mr. M. R. J. HAYES said that a negative showed detail more clearly than a reproduction would do. In the first case the line of incision through the body of the left pubic bone could be traced in the skiagram. There was bony union. In the President's case the line of incision, obliquely downwards and inwards, was also well marked. The patient was able to walk, although as yet there was no union. In the third case there was three-quarters of an inch separation between the fragments, with fibrous union. The fourth case had a symphysiotomy, the pubic articulation being indistinct, apparently from callus formation. The separation between adjacent portions of the pubis was more marked below than at the upper margin. The fifth case was one of pubiotomy and symphysiotomy, the pubic articulation being indistinct here, also apparently from callus formation. The line of pubic incision was vertical and the separated portion was in three fragments, suggesting a comminuted fracture. In the sixth case the incision ran downwards and inwards. The upper and inner fragment had been cut off, and there was fibrous union. The case was almost a symphysiotomy. In the seventh case the line of incision could not be traced; there was no doubt as to the bony union. In the last case the incision ran through the lower ramus of the left pubic bone. There was bony union.—Professor ALFRED J. SMITH thought that Dr. Tweedy's arguments and Mr. Hayes's skiagrams had made out a strong case. One case of bony union with a subsequent normal delivery was very interesting; in this case there was no evidence of increase in size of the pelvis. He would certainly stand by Dr. Tweedy in opposing English opponents of pubiotomy.—Sir WILLIAM SMYLY said that the operation recommended itself strongly to him, and he thought it superior to symphysiotomy. In some cases one was limited to either pubiotomy or extraperitoneal Cæsarean section. It was instructive to see how well the women walked.—Dr. GIBBON FITZGIBBON remembered one of Dr. Tweedy's cases, a symphysiotomy being done. The woman had since had three children. The second and third, one of whom weighed 9 pounds, were delivered naturally, but in the fourth pregnancy an extraperitoneal Cæsarean section had to be done. He asked if the skiagram showed anything to account for this, such as callus formation. The interval between the symphysiotomy and the Cæsarean section was four or five years.—Dr. A. N. HOLMES said that Dr. Tweedy's splendid series completely proved that pubiotomy would stay as a definite operation in midwifery. There was doubt whether bony union was better than fibrous as regarded future delivery.—Dr. T. NEILL had delivered one woman, the subject of a previous pubiotomy, of two subsequent healthy living children by induction of premature labour.—Dr. TWEEDY, in replying, said that the operation was not only successful, but it was the easiest operation one could perform, and any well-informed modern general practitioner who could attend a midwifery case in a proper manner was competent to perform it. The trouble that had followed on it in other cases was due, not to the pubiotomy, but to tearing of the cervix or vagina. The ordinary operations undertaken by the general practitioner were more difficult than pubiotomy.—The PRESIDENT, in replying, said that while the subcutaneous operation might be preferable, he was doubtful as to the advantages gained in using a sharp needle. In view of his want of experience he had not performed Bumm's operation, but had made an incision large enough to admit his finger.

Dr. KATHARINE M. N. MAGUIRE read a paper on a case of Cæsarean Section for Eclampsia.

Sir WILLIAM SMYLY read a paper on the Treatment of Eclampsia.—Professor SMITH warned his hearers not to think that eclampsia occurred only before delivery; a large percentage of cases occurred afterwards, and he had seen a case occur six days afterwards in a patient who had had a perfectly natural confinement, but whose typical scanty urine a few days later was loaded with albumin. Yet that patient was being cared for by excellent practitioners who followed the rules of treatment regarding fluids and diets. She had had no trouble in four previous deliveries. The source of the active cause of eclampsia had not yet been discovered and there were probably many causes. A run of cases at the Rotunda had all got well under the standard treatment by potassium bromide with chloral or chloroform, but later they had had a run of bad cases on which this treatment had no effect. The object should be to discover the origin of eclampsia and standardise the treatment.—Mr. A. J. HORNE quite agreed that cases occurred in cycles, and got well under a particular treatment that failed in other cycles. He instanced a case of a five and a half months' pregnancy in which convulsions occurred, and amaurosis lasting three months followed. Convulsions recurred at the confinement. He said that convulsions after labour were comparatively rare. He had adopted Dr. Tweedy's treatment of morphia, rectal injections, and mammary injections, and he believed in large doses of morphia.—Dr. TWEEDY believed that the food eaten was the primary factor in the disease, but other predisposing factors were at work—e.g., insufficient fluid intake into the system. No death had occurred in the last 30 eclampsias, covering three years, at the Rotunda. When the disease had once developed even milk sometimes initiated the convulsions, and he had evidence suggesting that an anaphylactic condition in respect to food was established. Absolute starvation was the treatment. If the fits recurred repeatedly the patient was turned on to the right side, to allow the outflow of mucus from the mouth. If the patient got blue she was turned over face downwards, and a flow of mucus followed by a gasp for breath ensued. For fear of "laking" of the blood he substituted bicarbonate of soda for sodium chloride (as used for years in diabetic coma), half a drachm in a pint of water for mammary injections. Repeated bowel lavage until action occurred and saturation of the system with morphia were practised. In his fatal cases death always took place a considerable time, from 5 to 45 hours, after labour. As long as milk was given the patient was not treated successfully, because she was saturated with some poison and needed absolute rest. If a woman was about to die, he performed Cæsarean section, abdominal before labour, but vaginal during it, for the preparation for the former was very long and deleterious. Chloroform was a deadly drug in hepatic inefficiency, and ether had its dangers. Delivery through the vagina could be done without a general anæsthetic.—Dr. W. M. CROFTON criticised Dr. Tweedy's remarks about the ingestion of milk. In the nephritis of pregnancy there was high blood pressure, and the administration of nitrites caused disappearance of albumin, and there was no eclampsia when labour came on. He wished to know from Sir William Smyly whether there was much bleeding in his cases at the time that eclampsia came on, because it had been noted that the fits stopped at once on a large bleeding. The bleeding should be continued until blood pressure became normal.—Mr. J. S. SHEILL said that though there was no reasonable doubt that Dr. Maguire's case was one of eclampsia, still there was a possibility that it might have been uræmia or cerebral hæmorrhage. He cited a case in point. He agreed that it was desirable to use more morphia and scopolamine. He did not consider Dr. Tweedy's milk theory proved.—Dr. R. D. PUREFOY said that for many years free venesection was the regular treatment in Dublin for eclampsia, and many recoveries took place. He thought it valuable in the early stages. The argument against the emptying of the uterus was that the convulsions did not always cease after it had been done.—Dr. NEILL referred to the present tendency against giving milk in enteric fever, and asked if whey would be better; to which Dr. TWEEDY replied that fits had come on after whey.—Dr. FITZGIBBON said that an analysis of the cases in Sinclair and Johnston's "Midwifery" showed that the results seemed better when purgation and venesection were practised than when venesection was practised alone. He mentioned a case comparable to that cited by Mr. Sheill, and suggested that violent eclamptic fits had brought on hæmorrhage.—The PRESIDENT held that it was futile to look for one cause to explain all cases of eclampsia. To search for the origin of eclampsia was like searching for the origin of the Nile, which came out of a lake, which in turn was fed by a number of rivers. He thought there was great obscurity about the origin of eclampsia. He suggested in reference to Dr. Tweedy's large number of cases that perhaps some of them could not properly be classified as eclampsia.—Dr. TWEEDY defined eclampsia and said that no cases were

included which did not comply therewith.—Sir WILLIAM SMYLY and Dr. MAGUIRE replied.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A clinical afternoon meeting of this society was held on Jan. 18th, Mr. W. Morley Willis, the President, being in the chair.—The following cases and specimens were shown:—Dr. C. H. Cattle: 1. A man, aged 53, with Argyll-Robertson Pupils, loss of knee-jerks, but had not had "lightning pains." He complained of some weakness and coldness in the feet. Six months ago he said he was very anæmic, but anæmia was no longer evident. 2. A woman, aged 37, suffering from Tabes, which was ten times more common in men than women. 3. A youth, aged 19, who had Weakness of the Legs, Exaggerated Knee-jerks, and Tremor of the Lips and Tongue, causing difficulty of speech. He attributed his illness to "a fall" five months ago. His cerebro-spinal fluid showed excess of lymphocytes and gave the Wassermann reaction. Suggested diagnosis: commencing general paralysis of the insane (juvenile form).—Dr. J. W. Scott: Child with Transposition of the Viscera.—Dr. W. T. Rowe and Mr. C. H. Allen: A patient after operation for Suppurating Hydatid of the Liver.—Mr. Kenneth Black: 1. A rare case of Rupture of the Small Intestine and Laceration of the Left Kidney. Operation; recovery. Subsequent formation of two large calculi in the damaged kidney; nephrolithotomy; recovery. Since the last operation further calculi had formed in the same kidney. 2. A case of Gangrenous Meckel's Diverticulum in a strangulated hernial sac. Excision of diverticulum; radical cure of the strangulated hernia; recovery. 3. A case of Otitis Media with Acute Mastoid Abscess and complicated by subdural abscess in the middle fossa of the skull and a similar abscess in the posterior fossa of the skull. Operation; recovery. Specimens: X ray photographs of: (*a*) Polyarthritis Deformans of the Hand. (*b*) Ununited Fracture of the Lower End of the Humerus; advisability of excision of the elbow-joint. (*c*) Pott's Fracture—27 years old. (*d*) Gonorrhœal Arthritis of the Shoulder-joint.—Mr. E. Bigg: A boy with an old Tubercular Knee, who had been treated by a bone-setter three years ago, when the right knee was flexed to a right angle and fixed in bony ankylosis. Left knee also flexed in compensation to nearly the same extent. He presented the appearance of a dwarf, and was incapable of earning his living. Mr. Arbuthnot Lane operated on the right knee two years ago, and made a diagonal saw-cut through the ankylosed joint securing the present position of the joint. The result was displacement of the lower part of the leg outwards, but with a minimum of shortening. The boy could now ride a bicycle and was employed as a mounted telegraph messenger.—Mr. A. R. Tweedie: A child, aged 4 years, showing repair after Acute Septic Periostitis and Necrosis of some three inches of the shaft of the femur. Specimens: (*a*) Sequestrum representing posterior wall of the External Auditory Meatus and Outer Wall of Antrum, illustrating Nature's attempt at the radical mastoid operation; (*b*) specimens of Tonsils removed by enucleation; and (*c*) sections of the Lingual Prolongation of the Tonsil.—Dr. J. Watson: 1. A married woman, aged 43. Choledocholithotomy on April 17th, 1910, for history of 20 years' "indigestion pain" and gall-stone attacks. No vestige of gall-bladder found. Stones in dilated bile duct and hepatic duct. 2. Carcinoma occupying left axillary border with glands in armpit. Tumour with pectoral muscles and axillary contents removed April 23rd, 1907. 3. Cancer of Right Breast; axillary side freely moveable. Breast tumour removed Dec. 2nd, 1907, and four days later muscles and fat from axilla. 4. Carcinoma of Left Breast with Glands in Armpit. Breast, pectoral muscles, and axillary fat removed November, 1910.—Dr. O. H. Isard and Dr. F. H. Jacob showed a specimen of Congenital Hypertrophic Stenosis of the Pylorus in a child aged 3 months. When the child was a month old vomiting commenced. There was usually only one large vomit per day, and occasionally there were two. Vomit was sour and curdy. Bowels were constipated. There had been marked wasting. Breast-fed for five weeks. Different kinds of foods had been tried since, but none were satisfactory.—Dr. Jacob showed a probable case of Congenital Heart Trouble in a boy aged 4 years. Loud systolic murmur was heard at base of heart, not at the apex, also in both axillæ and all over the back. Murmur was loudest in right axilla on lying down; loudest at angle of left scapula on sitting up. Pulse 92, irregular, and very feeble. Liver edge felt one finger's breadth below costal margin. Child appeared to be quite well.—Dr. Jacob and Mr. Tweedie showed for diagnosis a patient with a swelling which commenced on the right side of the chest last August and had grown rapidly lately. It was painful only when touched. It extended over the anterior portion of the chest, from the clavicle to the level of the diaphragm and from mid-axilla to mid-axilla; the skin was of an unusual colour, and in the upper part resembled a raw beef-steak, showing minute telangiectases; in the lower portion it was yellowish-blue like a dying bruise. The colour could be only partially removed by pressure. The upper portion was finely papular to the touch, was indurated and thickened, and did not move so freely on the chest bones as was normal.—Dr. Jacob showed a case of Idiopathic Muscular Atrophy in a boy, aged 9 years, who had been noticed to walk badly for some years, and had never walked quite properly. He now presented the typical lordosis and "climbing up his own legs" of the pseudo-hypertrophic form, but did not show the pseudo-hypertrophy or the weakness of the shoulder muscles; weakness of the orbicularis palpebrarum and other face muscles was, however, present.—Dr. E. Ringrose and Dr. Jacob showed a case of Sulph-hæmoglobinæmia. The patient had been blue, short of breath, and subject to severe headaches for some ten years. The spleen was enlarged and could be felt about two inches below the costal margin. The blood showed the spectrum of sulph-hæmoglobinæmia, which was very like that of methæmoglobinæmia, but the bands were in a slightly different position and were not removed by ammonium sulphide as were those of methæmoglobinæmia.

MANCHESTER PATHOLOGICAL SOCIETY.—A meeting of this society was held on Jan. 18th, Mr. J. W. Smith, the Vice-President, being in the chair.—Dr. W. Dyson gave an account of his Researches on Skin Pigmentation. He showed by means of the bichromate-hæmatoxylin method of Lorrain Smith and Mair that pigment is always formed as part of a complex granule which contains a lipoid substance. These granules are present constantly in the basal epithelial cells, and are formed there under the influence of the nucleus as a part of the normal metabolism of the cell. The pigment is in origin a lipochrome, the melanin being the chromatic proteid portion after separation from the complex lipoid granule. He found no evidence of pigment formation in the cutis, but showed sections which illustrated the passage of lipoid substances from the epidermis into the cutis along lymphatic channels. An increase of pigment can take place in two ways: 1. By the stimulation to increased activity of the epidermal cells by various agents (light, heat, toxæmic conditions, &c.). This pigmentation is transitory in character, and if the stimulus ceases the pigment gradually disappears. 2. By deficient drainage, due to obstruction of the lymphatics of the cutis. The normal amount of pigment being formed, it is unable to escape as quickly as it is elaborated, and therefore accumulates. This form of pigmentation is permanent and has a tendency to become progressively worse.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 17th, Dr. W. Mitchell, the President, being in the chair.—Dr. James Metcalfe read a paper on Electricity in Neurasthenia. He wished to bring before the society the uses of high-frequency currents, or D'Arsonvalisation, and static electricity in the treatment of neurasthenia. The symptoms of neurasthenia were described at some length under the headings of general and local. A description of the apparatus used, with diagrams, was given, and their mode of application was considered. Where the neurasthenia was associated with marked metabolic deficiency, or of the gastro-intestinal type, high-frequency currents were usually the most effective. But if the symptoms pointed more to a condition of a pure neurosis, static electricity acted best. The ordinary methods of treating neurasthenic patients were not considered, as the cases given had all been subjected to the usual forms of treatment by the medical practitioner who referred them for special treatment. Numerous cases were given of both men and women who had suffered from neurasthenia for long periods. The irritability, depression, insomnia, pains, and various other symptoms disappeared after from 12 to 20 applications of the

electrical currents. It was not to be assumed that electricity cured every case of neurasthenia, but it was well to remember that in cases where every other remedy failed there was a possibility of cure by these methods. The question was considered as to how these currents produced the therapeutical effect. Several of the cases on examination by a Riva-Rocci sphygmomanometer showed a high blood-pressure, and it was observed that the application of the currents caused a reduction of the tension and, *pari passu*, an improvement in the disease. Nearly all the cases treated had been permanently cured. Probably the effect was produced by stimulating general metabolism, and in this way effecting the elimination of toxic agents, or by a direct vaso-motor action on the vessel walls themselves. Possibly the inhalation of ozone generated by these machines had some influence in improving the patient's condition. Psychic influence was no more common in this form of treatment than by the use of ordinary remedies. D'Arsonval and others had been able to demonstrate increased tissue changes, more rapid reduction of the oxyhæmoglobin in the blood, and increased elimination of waste products in the urine. There was also a profound action on the protoplasm of cells everywhere, increasing their chemical changes.—The paper was discussed by the President, Dr. S. Lodge, Dr. F. W. Eurich, and Dr. A. Bronner.—Dr. Metcalfe then replied.

HARVEIAN SOCIETY OF LONDON.—A clinical meeting of this society was held on Jan. 26th at the Paddington Green Children's Hospital, Mr. J. Ernest Lane, the President, being in the chair.—The following cases were shown by the President and members of the hospital staff and others:—Dr. Leonard G. Guthrie: Case of Hydrocephalus.—Dr. Guthrie and Mr. M. S. Mayou: Case of Pseudo-glioma.—Dr. G. A. Sutherland: Cases of (1) Cerebellar Disease; and (2) Fibroid Phthisis.—Dr. Frederick Langmead: Cases of (1) Urticaria Pigmentosa; (2) Congenital Heart Disease; and (3) Myositis Fibrosa and Sclerodermia in an infant.—Dr. Reginald H. Miller: Cases of (1) Raynaud's Disease; and (2) Polio-encephalitis.—Mr. A. Edmunds: Cases of (1) Hypospadias; and (2) Cyst of the Humerus.—Dr. G. de B. Turtle: Case of Pyloric Spasm.—The President: Two cases of Syphilis treated by "606."

# Reviews and Notices of Books.

*A Text-book of Zoology.* By T. JEFFREY PARKER, D.Sc., F.R.S., and WILLIAM A. HASWELL, M.A., D.Sc., F.R.S. In two volumes. London: Macmillan and Co. Vol. I., 839 pp.; Vol. II., 728 pp. Price 36*s.* net.

THERE are nowadays so many text-books of zoology that to have arrived at a second edition is somewhat of a triumph, and is at least a handsome testimonial on the part of the scientific public. Among such text-books of zoology, which have evidently established for themselves a firm place in the literature of biology, Parker and Haswell's work occupies by no means an obscure situation. Not only is it dependable by reason of its accuracy, but it is unlike many other contemporary works which cover the same, or about the same, ground. The plan of the present work (which has not departed in this from the first edition) is to preface the accounts of the various groups of animals with a more or less detailed *résumé* of the anatomy of one particular example selected for various considerations as representative of that group. The authors are well advised, in our opinion, to drop the misused, or at any rate somewhat misunderstood, word "type" describing the particular animals which they select to represent the main groups of the animal world. The word "type" implies more than is commonly in the mind of those who make use of this term. "Example" is a far more expressive way of putting the idea suggested. The authors acknowledge their indebtedness for this emendation to Dr. Hill, lately Master of Downing College, Cambridge, and rightly assert that the student is apt to take the structure of the type for that of the group of which it is only an example, and, maybe, even a specialised and thus not typical example.

It is occasionally the practice of reviewers to seek for what is not contained in a book, rather than to express an opinion as to what the author has judged suitable and necessary for insertion. In a work dealing with so colossal a subject as is zoology at the present day, it would be the easiest of criticisms to point out the absence of this fact and of that, of one genus or of another. In fact, within reasonable limits—and two volumes containing between them nearly 1600 pages cannot be fairly considered as unduly short—it is not even within a distant approach of possibility to abstract the whole of the facts of zoology.

Nor has this science stood still during the 12 years since the publication of the first edition. Thus the problem which had to be faced by the author of the second edition (for it is now some years since the death of that very talented anatomist Jeffrey Parker) was by no means how to fill two volumes with the facts and chief inferences of zoology, but what might be safely omitted. Dr. Haswell, keeping to the original plan, has saved space by dealing very briefly with the smaller subdivisions of the larger classes, and by not burdening the student with a long series of names and definitions of the characters of the members of these smaller subdivisions. In fact, the book is essentially for the commencing student and not for the student who has already begun to specialise. In making this statement, however, it must not be supposed that Dr. Haswell has limited his survey to the well-known and often-trodden paths of zoology. He has introduced a great number of more recent researches such as have appeared since the publication of the first edition, while not neglecting the more familiar facts known to us for many years past. Thus, there is a figure of that remarkable crustacean, Paranaspides lacustris, from Tasmania, lately discovered and studied by Mr. Geoffrey Smith of New College, Oxford, an animal which is nearly related to certain very old fossils, and serves to link together more specialised groups of crustacea by its "generalised" characters. Place is also found for the very interesting and probably very important views of Dr. Goodrich of Merton College upon the relations between the true nephridia and the "cœlomo-ducts" in Annelids, and indeed in animals generally. Other examples might be mentioned which prove that the author has kept a critical eye upon the progress of zoological research, and not only in those groups in which he himself is particularly interested and to our knowledge of which he has contributed.

The vertebrata, together with certain primitive and allied forms such as the Ascidians, occupy an entire volume to themselves. For practical purposes this is necessary, since in every way the vertebrata bulk more largely than does any other great group of the animal kingdom; but on more theoretical grounds, for the range of structural variation in this group is not so great as in such a group as the Echinoderma or the Annelids (in a broad sense), one might criticise the undue importance thus given. However, as already remarked, it is impossible to include everything in a text-book of finite dimensions and if one group is to receive more generous treatment than another that group should be, and as we think from every point of view, the group of the vertebrated animals. A feature of this text-book, as compared with some others, is the large number of illustrations of the external form of vertebrated animals, particularly of mammals; and we note that a good many of the excellent drawings by Mr. Dixon, which adorn that volume of the "Cambridge Natural History" which deals with mammals, are utilised by Dr. Haswell for his present purpose. Writing from the Antipodes, and partly, no doubt, with the interests of Antipodean students in his mind, it is not surprising that Dr. Haswell

should dwell wherever possible upon the zoology of Australasia. It is curious, therefore, to observe that among the very few errors which we have noticed in looking into this work is a decided lapse with regard to the Australian ant-eater, Echidna. One of the rather long series of structural facts which almost seem to justify the placing of this creature together with the Ornithorhynchus in a group equivalent to that which should include the rest of the mammalia, concerns the structure of the heart. It has been shown by more than one observer that the right auriculo-ventricular valve in Echidna is not only an incomplete valve surrounding little more than half of the aperture, but that it is largely muscular and not membranous in character. But we find on p. 575 of Vol. II. the statement that "In Echidna the tricuspid valve is completely membranous." This is, however, possibly a misprint, or *lapsus calami*, for bicuspid, in which case the peculiar characteristics of the right heart valve are not mentioned.

Nor can we quite agree with the definition of the order Squamata, including the lizards and snakes, as characterised (*inter alia*) by the possession of lungs which are simple sacs. This is undoubtedly true of the majority, but the statement does not at all apply to the monitor lizards, which are so different in many particulars from other lizards, and in which Reptilia the lungs are quite as complicated by a sub-division of their cavity as they are in a crocodile or a tortoise. It is very remarkable to find amongst the monitors, which are unquestionably lizards, certain structural likenesses to the Crocodilia; these may perhaps be correlated with their at least occasionally aquatic life.

While presenting the reader in the main with the facts of zoology, the author does not neglect the more theoretical aspects of biology, and in this respect there is no change made from the first edition. The section of the work which deals with such problems is, however, commendably short, as the beginner ought to be sternly kept to facts until he is in a position to utilise this knowledge for the consideration of hypotheses. We are glad to see that in the pages which deal with "The Philosophy of Zoology" the question of "Orthogenesis" is not ignored. The American palæontologists more particularly have dwelt upon the fixed and, so to speak, "pre-arranged" lines upon which evolution has proceeded in certain cases. Thus quite independently of useful modifications (we are disposed to think), the horse tribe have persistently followed, from the Eocene down to the present day, a continuous reduction and ultimate shedding of the fingers and toes, resulting in the one-toed horse of recent and modern times. Dr. Haswell does not indicate that he holds any brief for any specified view—an attitude which is to be praised in a teacher whose business it is to present the facts and inferences to his pupils and not to direct their conclusions. Finally, we may call attention to the bibliography which closes the second volume. This is a well-selected list of general works, and no special monographs or memoirs in journals or the publications of societies are referred to.

Considering the enormous mass of zoological fact and literature available to the author, it is quite wonderful what a great deal has been found room for in these two most useful volumes.

---

*Urinary Surgery: A Review.* By FRANK KIDD, M.B., B.C. Cantab., F.R.C.S. Eng., Assistant Surgeon to the London Hospital. London: Longmans, Green, and Co. 1910. Pp. 429. Price 7*s.* 6*d.* net.

MANY medical men, especially if they have not qualified within recent years, are quite unaware of the enormous progress that has been made in the surgery of the urinary organs, and Mr. Kidd has written this book for the purpose of drawing attention to the very great advances both in diagnosis and treatment which have been recently achieved. The progress made during the last ten years may be divided into four categories. In the first place, catheterisation of the ureters is a much simpler matter now than it was ten years ago; and, further, we are able at the present day to form a very accurate estimate of the physiological power of each kidney, so that the danger hardly now exists of removing the better kidney of the two. The development in the bacteriology of the urine and of the urinary tract has added greatly to our knowledge of infections of this system, and has enabled us to do more in treatment. The introduction of the X rays for the detection of calculi in the kidney, the ureter, and the bladder has added enormously to the diagnostic powers of the surgeon. Lastly, the great development of the surgery of the prostate has placed in our hands a wonderful influence for good in cases which were, at one time, most difficult to treat. All these, and many more, aspects of the modern urological surgery will be found described in this book. Its arrangement is excellent and it is easy to read.

*Cunningham's Manual of Practical Anatomy.* By the late D. J. CUNNINGHAM, M.D. Edin. et Dub., D.Sc., LL.D. St. And. et Glasg., D.C.L. Oxon., F.R.S., late Professor of Anatomy in the University of Edinburgh. Fourth edition. Revised by ARTHUR ROBINSON, Professor of Anatomy in the University of Edinburgh. In two volumes. Vol. I.: 624 pp. and 237 illustrations; Vol. II.: 600 pp. and 236 illustrations. London: Henry Frowde and Hodder and Stoughton. 1910. Price 10*s.* 6*d.* net per volume.

THIS work has so long enjoyed a wide and well deserved popularity that its general merits do not fall to-day within the scope of an ordinary review. The appearance of four editions, each of which has marked a distinct advance on its forerunners, is, in itself, a guarantee that Cunningham's Manual provides the student with a guide to the dissection of the human body which admirably fulfils its purpose. Indeed, there appears to be a tendency on the part of the student to regard "little Cunningham" as a text-book, as well as a dissecting manual. The amount of accurate information contained within its 1200 pages would almost seem to justify this view, and concerning all those structures which may be fully examined in an ordinary dissecting-room subject the student will need to do a minimum amount of additional text-book reading, if he studiously follows the manual in his actual practical work. During the life of its author—the late Professor D. J. Cunningham—four editions of the work appeared, and the advances marked by these four successive issues are very remarkable, for the first edition was an ancestor of very modest appearance. Professor Arthur Robinson, the successor to Professor Cunningham in the historic chair of anatomy in Edinburgh, is responsible for the present volumes, and he has been assisted in the work of revision, as was Professor Cunningham, by Dr. E. B. Jamieson, lecturer in anatomy at the University.

This present issue, although described as merely a revision of the fourth edition, contains sufficient new features to justify a critical review of the alterations which have been made. Perhaps the greatest innovation is the tardy introduction of the B.N.A. terminology, of which a glossary is given at the beginning of each volume. In the present unsatisfactory transition stage of the nomenclature used by British anatomists, it cannot, perhaps, be expected that the book should have naturally dropped into the new ways all at once; but it is to be hoped that every future edition of the manual will help to stereotype the universal nomenclature in the leading British dissecting guide.

Some new illustrations have been added, and some of the old ones, which were plain black and white in former editions, have been coloured in the present issue. It is possible that different copies vary in the excellence of the

colour reproductions, but in those which the reviewer has examined the printing of some of the more highly coloured figures does not seem to be quite satisfactory, for in some cases in which colour has been added to an old black and white drawing there is a certain degree of overlap. A word must also be said with regard to some of the pointing lines used for naming the structures in certain illustrations. A method of dotting these lines has been adopted in some cases, and this cannot be considered as an improvement on the plain ruled line used in the older plates, for it is often very difficult to determine on what structure the pointing line actually stops. In practical use this state of affairs has proved, we know, a stumbling-block to students. In Vol. II. Fig. 78 (repeated as Fig. 83) is an example of this fault, for the pointers intended to indicate the internal carotid artery and the internal jugular vein both lead to other structures, while the pointer which rests on the ramus descendens hypoglossi remains unnamed. Fig. 81 (repeated as Fig. 91) has the same defect of uncertainty as to the termination of the index lines, and in Vol. I. Fig. 231 shows a wrong index to the sacral plexus, while in Fig. 212 the red index lines lead to confusion, especially in the case of the lower pointer to the levator ani muscle. These defects are easily remedied, and since demonstrators have on many occasions been questioned by students to whom they had caused some anxiety they are cited, not as a criticism of the work, but as a guide for the author in future revision.

The other marked changes introduced in this issue are mainly concerned with the pelvis and its manner of study, and Professor Robinson has done wisely to alter the route of dissection. Perhaps in some future edition there will be more sweeping changes in this portion of the book, for the pelvic fascia is capable of still further simplification in the light of a mass of modern work on the subject; and the inclusion of some description of the musculus recto-urethralis would constitute an added improvement, since the muscle has taken its place in English surgical literature. In some other respects the book might be modernised with advantage, and we are tempted to regret that Professor Robinson did not make the description of the testicle and its method of descent conform more to the requirements of modern research, especially since these things have been rendered familiar to English students by the work of Dr. D. Berry Hart in Edinburgh.

Professor Robinson is to be congratulated upon the appearance of these volumes, which mark the high-water level of Cunningham's Manual; and such criticism as we have levelled against them must be regarded merely as suggestive of improvements which will help to maintain the book in its well-deserved position as the premier dissector's guide for the student of human anatomy.

---

*A Study of the After-results of Abdominal Operations on the Pelvic Organs, based on a Series of 1000 Consecutive Cases.* By ARTHUR E. GILES, M.D., B.Sc. Lond., F.R.C.S. Edin., Surgeon to the Chelsea Hospital for Women. London: Baillière, Tindall, and Cox. 1910. Pp. 252. Price 10*s.* 6*d.*

AS the author of this work points out, of late years recovery from an abdominal operation has become almost a matter of course, and how small the mortality may be is shown by his own figures giving a mortality of 6·6 per cent. for the first 500 cases and one of only 1·6 per cent. for the second 500. In these conditions the most important question at the present day is not the immediate mortality of such operations but the after-results to the patients. For the purpose of attempting to give an answer to this question Dr. Giles has collected as far as possible the results of his work, and this book contains these results and the conclusions he draws from them. Such an investigation when carried out by the operator himself is, of course, always open to the grave objection that he is by no means the best judge of the after-condition of his patients. The personal equation must enter into an inquiry of this kind; and the tendency to exaggerate the benefits gained, and to minimise the bad effects resulting, from any operative procedure must be so powerful as inevitably to vitiate to some extent the conclusions formed even by the most impartial of observers. For this reason we are inclined to lay much greater stress upon the after-histories of patients when they are recorded by some observer other than the surgeon himself. None the less, Dr. Giles deserves great credit for the labour he has expended and for all the time and trouble he has devoted to this task, and the results are certainly valuable even if we feel that we cannot accept all his conclusions without some slight amount of hesitation.

The first part of the book is concerned with the after-results of each operation considered in detail, and the second half contains in tabular form a complete record of the patients. As the book is a reprint of a series of articles which appeared in the *British Journal of Obstetrics and Gynæcology* no doubt most gynæcologists who are interested in these matters have already read its contents. If we look at the conclusions as to the general health of all patients after abdominal operations we find, according to Dr. Giles, that no less than 90 per cent. were better than they had been before the operation, and only 6 per cent. were either worse or at least no better.

The operation of hysteropexy appears to be a very favourite one with the author, since he has practised it no less than 309 times in his 1000 cases. In curious contrast to this frequency is the comparatively small number of times this operation figures in some of the records of the gynæcological departments of our large hospitals with medical schools attached, where it appears to meet with but scant favour.

---

*Biology, General and Medical.* By JOSEPH MCFARLAND, M.D., Professor of Pathology and Bacteriology, Medico-Chirurgical College of Philadelphia. With 160 illustrations. London and Philadelphia: W. B. Saunders Company. 1910. Pp. 440. Price 7*s.* 6*d.* net.

THIS volume cannot fail to be of great interest to two classes of readers. The biological part provides an excellent and readable summary of the elements of biology for general readers who have had little or no special training in this science, while the more specialised medical aspects of the subject will afford to general practitioners of medicine a broad but accurate survey of various fields of new knowledge, such as immunity and senescence. Professor McFarland has undertaken a tremendous task in trying to condense into one volume such a large range of subjects, but his wide knowledge, both of general biology and of pathology, has enabled him to grapple with it in a most successful manner. After a historical sketch of the theories which have dealt with the origins of life in all ages, some 200 pages are devoted to a sketch of the manifestations of life in various plants and animals, the function of cells, the reproduction of cells and of individuals, and similar well-known biological phenomena. This section of the book might have been fuller, but it would have been impossible to make the picture complete, and the author has shown a wise discretion in his selection of illustrative functions. Several chapters follow dealing with the difficult subject of modern theories of descent, transmission of type, and heredity. The treatment of this matter is luminous and broad, in spite of the limited space at the writer's command. A short but lucid chapter on "blood-relationship," a term adopted from Nuttall, serves as an introduction to a study of infection and immunity, and is

one of the best bits of work in the book, which closes appropriately with a review of the work of Metchnikoff, Minot, and others on senescence and decay. In spite of the technical character of much of the subject-matter the style of writing is easy, simple, and direct, and there are very few Transatlantic peculiarities of diction. The printing is excellent, and the volume is light to hold, no small virtue in these days of loaded paper, while the illustrations are numerous and useful.

---

*Le Cancer.* Par le Docteur JOSEPH THOMAS, Docteur ès Sciences. Deuxième édition, revue et augmentée. Préface du Professeur ALBERT ROBIN, Membre de l'Académie de Médecine. Paris: A. Maloine. 1910. Pp. 376.

Dr. Thomas published in 1906 the first edition of his short history of cancer, and since that time a very large number of papers and volumes have appeared on the subject of cancer, some of which, even when of much importance, are likely to be missed by those interested in the study of this disease. It is of great value to have a volume in which the reader can be sure of finding a reference to most papers of importance on the subject. The book is very complete: in it will be found all the different theories which have been put forward to explain cancer, and an account of the pathological histology, the signs and symptoms of the disease, the question of contagion, and the treatment. The vast differences which exist in the frequency of the disease in different parts even of the same country are shown in a table taken from the thesis of Fabre. This demonstrates that while at Havre 71 persons die from cancer each year per 100,000 of the inhabitants, at Paris 104 die, at Saint Sylvestre 345 die, and at Oulchy 1400 persons die. Many similar facts of interest will be gleaned from this volume, and we commend it to all who are studying this important malady as a convenient manner of keeping before them an all-round survey of the subject.

---

*Transactions of the Medico-Legal Society for the Year 1909–1910.* Edited by DIGBY COTES-PREEDY, M.A., LL.M., L.S.A., Emmanuel College, Cambridge, of the Inner Temple and Oxford Circuit; Barrister-at-Law; and WILLIAM A. BREND, M.A., M.B., B.Sc. Lond., of the Inner Temple; Barrister-at-Law; Lecturer on Forensic Medicine, Charing Cross Hospital. Vol. VII. London: Published for the Society by Charles Griffin and Co., Limited. 1910. Pp. 186.

SINCE its foundation in 1901 the Medico-Legal Society has conducted many interesting discussions upon subjects of considerable public importance, some of which are not easy to ventilate satisfactorily in any gathering composed exclusively of medical men or of lawyers, or by any means not directly conducive to the friendly exchange of divergent opinions. The membership of the society now amounts to well over 200, and it is to be hoped that the loss which it has sustained by the death of Sir Joseph Walton, who was one of its vice-presidents, may be made up to it by the accession of some other member or members of the judicial bench. There are many judges whose presence at the meetings of the society would add very considerably to their interest and to the weight of the conclusions arrived at, and there are few judges who by attending might not gain an insight into the reasons which lie behind contradictions of medical evidence, into the difficulties which beset the scientific witness, and into defects in the law to which they, as judges, above all others have the power to call attention. We refer to such papers (among those in the present volume) as the Mutual Relations and Influence of Law and Medicine, the subject of a presidential address by Sir John Tweedy, and the Effects of Traumatism on the Nervous System by Dr. J. S. Risien Russell, out of both of which can be extracted valuable expressions of opinion with regard to the desirability of the provision of medical assessors in cases which obviously demand their presence.

The papers read before the society, however, do not deal by any means always with matters tending towards legal reform, but in many instances are useful monographs followed by discussion from two points of view upon topics not exclusively medical, or entirely legal, and of interest to members of both professions. Thus that of Dr. F. G. Crookshank, on the Examination of Bodies Found in the River, contains practical hints from an expert to his fellow practitioners combined with points which any legal member of the society might some day find useful in the conduct of cross-examination at a criminal trial; and another "On Ferro-Silicon, with Special Reference to the Poisonous Gases Liable to be Evolved Therefrom," by Mr. H. Wilson Hake, may be referred to as an interesting summary of the history of a poisonous substance the transport and storage of which caused an astonishing number of deaths before its dangerous qualities attracted official attention.

---

## LIBRARY TABLE.

*Surgical After-treatment: a Manual of the Conduct of Surgical Convalescence.* By L. R. G. CRANDON, A.M., M.D., Assistant in Surgery at Harvard Medical School. With 265 original illustrations. London and Philadelphia: W. B. Saunders Company. Pp. 803. Price 25*s.* net.—The appearance within the last few years of several treatises on the after-treatment of surgical cases shows appreciation of the importance of this matter and recognition of the fact, which is only too often neglected, that with the completion of the operation the work of the surgeon has not ended. Another volume, therefore, on the same subject, while not perhaps absolutely needed, is at least an addition to a literature at present not overdone. Dr. Crandon's work is written on very sensible lines. He discusses first the details of the sick room, the recovery from anæsthesia and the treatment of its after-effects, the relief of thirst, of pain, and of insomnia. The various forms of post-operative hæmorrhage, of shock, and phlebitis are also considered; the diet after operation, rectal feeding, catheter isation, and various other post-operative complications and procedures are dealt with. The second part of the book concerns itself with operations on different parts of the body. The author recommends depilation by means of a depilatory paste in the preparation of a patient for operation, a method not sufficiently employed. It is much less disturbing than shaving is to the part, and it leaves the surface smooth, clean, and practically aseptic. The value of hot weak tea in diminishing the thirst after operation is not fully appreciated, and many nurses withhold it from their patients. It can often be retained when everything else is vomited. Many surgeons approve of its administration highly, and we are glad that Dr. Crandon has mentioned it in his work. The book contains much that will prove useful to the surgeon who is anxious to do the best he can for his patient, and we have formed a very favourable opinion of it.

*Diet and the Maximum Duration of Life.* By CHARLES REINHARDT, M.D. Brux. The London Publicity Company. Pp. 108. Price 1*s.* net. *The Food Reformer's Companion.* By EUSTACE MILES. London: Mills and Boon. Pp. 186. Price 2*s.* 6*d.* net.—Food reformers can be divided into two classes: those who base their desire for reform on the ground of humanity, and, like the conscientious Hindu, will eat nothing that involves the taking of sentient life, and those who are chiefly concerned, whether for altruistic or other reasons, in the maintenance of health. The fact that health is maintained by different nations on foods which

in their nature vary widely, to say nothing of the range in variety and quality of the foods used by the different strata of society in any one nation, proves that habit will enable man to live on almost anything. In the now almost forgotten treatise on temperance of Cornare, which was translated from the Italian by Master George Herbert, "of blessed memorie," the author sought to show that "intemperance was not such an evil but it might easily be remedied," the word intemperance, of course, being used in a wide sense. Dr. Reinhardt tells us that his book is not a sentimental work, nor a treatise on humanitarianism, but an effort to point out the nearest approach to the perfect way in diet; and the dual problem which he sets before himself of maintaining health and postponing the evils of old age resolves itself into the question of averting or preventing intestinal putrefaction. He discusses the various forms of diet, especially drawing attention to the evils of excessive meat eating, and arrives at the conclusion that strict frugality, thorough mastication, and the judicious employment of certain health-preserving foods, of which Bulgarian sour milk is the most notable, are the best means of attaining a healthy old age, Mr. Eustace Miles, who protests against being called a "vegetarian," since he eats fewer vegetables than most meat eaters, is also an advocate of thorough mastication, but the foods which he discusses have a less limited range than those of Dr. Reinhardt. Mr. Miles's book is a plea for what he calls a balanced non-flesh diet—that is, a diet without meat selected to suit individual idiosyncrasies. He appeals to various classes and various individuals and shows how meals, according to his system, can best be prepared by a man or woman living alone, or by the one non-flesh eater in a family, without serious inconvenience to other members of the household. The book contains some useful vegetarian recipes.

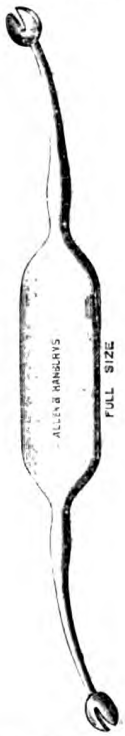
*Lehrbuch der Augenheilkunde.* By Various Authors. Edited by Dr. THEODOR AXENFELD, Professor of Ophthalmology in Freiburg. Jena: Gustav Fischer. 1910. Pp. 708 and 11 plates. Price, paper, 14 M.; board, 15 M.—Professor Axenfeld's text-book of Ophthalmology, which we reviewed in THE LANCET of March 27th, 1909, has already reached a second edition. The general structure of the work is maintained, the only notable changes being the sections on diseases of the lacrymal organs and on injuries and sympathetic ophthalmia, which were written by Professor O. Schirmer and now appear under the names of Professor Stock and Professor Hertel respectively. We had occasion in our review to point out the shortcomings of the ophthalmoscopic drawings. Many of the old ones are now transferred to the text, and the new set of plates is a very decided improvement.

*Radiometrie Fluoroscopique.* By Dr. H. GUILLEMINOT. Paris: G. Steinheil. 1910. Price 2 francs, 50 centimes.—This is a note on the author's method of fluoroscopic radiometry, based on the comparison of results when a platinocyanide screen is illuminated by the X rays and by a standard specimen of radium. Apart from the fact that a rather expensive specimen of radium is required for a standard, this method of radiometry is perhaps the best that has yet been devised. The standard consists of 20 milligrammes of radium bromide (activity 500,000) spread over a surface of 1·75 square centimetres on a copper disc and illuminates a screen placed at a distance of 2 centimetres. Dr. Guilleminot also describes a means by which specimens of radium for therapeutic purposes may be standardised and later used themselves as standards. He shows the advantages thus gained in radiography give much more uniform results and a great saving in time and plates. The third chapter is devoted to a study of the analysis of a polychromatic beam of the X rays as a basis of accurate treatment; and the final chapter is on the use of filters, which have done much to place radio-therapeutics on their present basis.

# New Inventions.

## COMEDO EXTRACTOR.

I HAVE had constructed for me by Messrs. Allen and Hanbury of Wigmore-street, London, W., a comedo extractor by means of which graduated pressure may be applied whilst the black head remains under observation. The instrument consists of a broad handle with a curved shank at each end terminating in a concavo-convex head with a V shaped neck or slot. The slots differ in size. The curved shank is so constructed that it adapts itself to all parts of the face. The shape of the slot enables a graduated pressure to be applied exactly around the blocked duct, whilst the slightly convex lower surface of the head allows an even pressure on the skin. The edge of the slot is bevelled and rounded, thus preventing any injury to the skin. The slightly concave upper surface allows each comedo to be removed after extraction quite easily, so that the slot may not become blocked. The method of use is to place the edge of the slot 3 millimetres (one-tenth of an inch) from the comedo, and to gradually advance it with increased pressure.



T. P. BEDDOES, M.B., B.C. Cantab., F.R.C.S. Eng.
Stratford-place, W.

THE ST. MARYLEBONE DISPENSARY FOR THE PREVENTION OF CONSUMPTION.—The committee and medical officer of the St. Marylebone Dispensary for the Prevention of Consumption were "At Home" on Jan. 25th, at the Dispensary, 15, Allsop-place, Upper Baker-street, N.W. The invitation was well responded to and a representative gathering of visitors were shown over the premises, and showed much interest in the principles and methods of work of this new organisation in the borough. The dispensary is on the lines of those already existing in Edinburgh, Paddington, and in Berlin, Montreal, New York, Boston, and Pittsburg. As the chief sources of infection exist in the homes of the people in our great cities, it is here that the dispensary attacks the malady at its source. To the dispensary, which is free to all, patients who are not already under a medical practitioner may go for examination, diagnosis, and treatment. From the dispensary a physician and nurse visit the homes of the patients, who are thus educated in open-air treatment and in the protection of others by the observance of a few simple precautions. The medical officer also examines all those who have been in contact with the patients, and thus some of the early cases are diagnosed while they are yet curable. In every department of its activity the dispensary works in coöperation with the public health authority, with the various charitable agencies in the borough, and also with the practitioner. The work is carried on by voluntary effort, and entirely supported by voluntary subscriptions, which should be sent to the honorary treasurer, St. Marylebone Dispensary for the Prevention of Consumption, 15, Allsop-place, London, N.W.

# THE LANCET.

*LONDON: SATURDAY, FEBRUARY 4, 1911.*

## The Present Plague Peril in China.

REPORTS recently received from China regarding the spread of plague in that country reveal a very grave situation. The note of warning was sent to us by our correspondent in Peking just before Christmas. The disease starting, it is said, in Mongolia has gradually extended into Manchuria, where at the present moment an extremely fatal and widespread epidemic has developed. From Manchuria the infection has already been carried southward to Chefoo and other places in the province of Shan-Tung, and to Tientsin and Yung-ping-fu, as well as to Peking itself in the province of Chi-Li. There are now indications that from these centres plague is diffusing itself in the interior of the Chinese Empire. Unhappily, the present prevailing type of the disease is the pneumonic, and this doubtless accounts both for the rapidity of spread and the excessive case mortality. At the Manchurian town of Mukden the latest accounts assert that more than 150 deaths from plague are occurring daily. Among the victims there are already included two medical men, one a Frenchman, Dr. MESNY of Tientsin, the other an Englishman, Dr. A. F. JACKSON, a medical missionary, both of whom had left their own work and volunteered for plague duty; also a lady doctor, Madame LEBEDEFF, has lost her life in attending upon plague patients. At Harbin, another Manchurian town north of Mukden, more than 1200 persons have lost their lives during a comparatively short period, and thousands of the panic-stricken inhabitants of the city have already fled seeking refuge in other towns and districts, and carrying with them the leaven of infection. Business is said to be at a standstill, and it is impossible in many instances to find the necessary labour to bury the dead; some corpses, deserted in the streets by their terrified relatives, are found half-devoured by dogs, and in the absence of any other available means for speedy burial they have been flung into the river that flows through the town. In the face of all this the Chinese officials in Manchuria have displayed for the most part an attitude approaching brutal callousness. In one instance representations made by the Russian consular authorities have succeeded in getting the Chinese Taotoi of the town dismissed from his post by order of the Peking Government. There is a very great scarcity of medical men in the plague-invaded district, and although Russian, Japanese, English, and other medical men have freely volunteered their services the number falls far short of what is imperatively required. Meanwhile, failing other skilled assistance, the students in the Chinese medical schools have been requisitioned by the Government for plague duty, and some of them have already fallen victims to the epidemic.

There are indications that by this time the Chinese Government has become thoroughly aroused, not to say alarmed, at the danger from the spread of plague in the Empire, but it seems to be at a loss to know what course to take. About a fortnight ago the Russian Foreign Office approached the Peking Government, as well as the other Great Powers interested in China, suggesting the organisation and despatch of an International Scientific Expedition into Manchuria to study on the spot the problems associated with the epidemic of plague. As a result we learn that the Chinese Government has now sent out a Circular Note to the Great Powers requesting their coöperation in discovering the cause or causes of the epidemic, and in devising appropriate measures to cope with it, and also as to conducting scientific investigations regarding the disease. The Great Powers, we understand, have been each invited to nominate a plague expert to serve upon the International Commission, and it is intimated that all expenses incurred by that body will be defrayed by the Chinese Government. We are not sure that a committee of scientific experts is the best organisation at the present juncture with which to fight the plague epidemic in China. Rather do we think that what is most needed is the establishment of an administration to formulate preventive measures and with power to enforce them. The bacteriology of plague and the various modes in which the infection is conveyed to man have been carefully studied by the Indian Plague Commissions as well as by other experts on the European continent and at home. It is, in our opinion, the practical application of all the acquired knowledge by able administrators rather than the advice of scientists that is most needed at the present crisis in order to arrest the sacrifice of human life that is now going on and which threatens to increase. Should an international commission of plague experts, nominated by the Great Powers, be despatched to China to deal with the epidemic, we fear that they will have a hard and up-hill task before them. In China there is at present no machinery for the notification of disease nor for registration of deaths; there is no existing sanitary service the officials of which could be trusted to carry out the measures framed by the international body of experts. There is, moreover, to be faced the deadweight of passive resistance and obstruction by the Chinese themselves. The Chinese, or many of them, are fanatics where their own habits and customs are concerned; they are still distrustful of the "foreign devils" and their remedies. At times, indeed, the distrust is apt to find expression in rioting and in the destruction of the foreigner's life and property. China, with its 400 millions of inhabitants, has not yet awakened to the need of sanitary progress, and many of its towns and districts are in a deplorable sanitary condition.

Every circumstance unfortunately seems in favour of the spread of plague, especially if introduced in the pneumonic form. Like other countries, China has more than its share of rats and other rodents, so that there is a distinct probability, if plague penetrates into the interior of China, that it will make a long stay and leave its mark on that country for years to come. China's cry for help will no doubt receive a sympathetic response from all the Great Powers. Immediate

action is obviously called for and will, no doubt, be forthcoming from the International Commission as soon as it is formed. The matter is one of the greatest urgency if the spread of plague into the interior of China is to be arrested. We have grave fears that if the epidemic goes on increasing at its present rate we may have to witness in China a sacrifice of human life compared with which even the Indian experiences may sink into comparative insignificance.

## Operating Without Skilled Assistance.

IN an address delivered before the Students' Medical Society in Aberdeen and published in our columns on Dec. 24th, 1910, Mr. G H. COLT drew attention to the necessity which occasionally arises for a surgeon to operate without the assistance which he would like to command. To those who are accustomed to have skilled assistants in operating it may appear difficult to perform extensive and serious operations with little help and even with none, or with help of an unskilled kind. It is on board ship that emergencies of this kind usually arise. Many a surgeon on board ship has to operate in cases of emergency with no more help than can be obtained from the passengers or crew. Say that an operation for appendicitis has to be done, and there is no anæsthetist on board. A stewardess, with certain instructions, has to carry out the administration of the anæsthetic, anæsthesia having been induced by the surgeon, who has to keep a watchful eye on the progress of the anæsthesia and the general condition of the patient. A passenger, perhaps, or one of the crew may be called upon to hold retractors, and generally sufficient assistants can be obtained who make up by willingness for their lack of skill. Should any of the helpers have assisted at a previous operation he feels that he knows the work, and is regarded by his fellow assistants as well-qualified to supply skilled help. The difficulties of performing an operation at sea are not small, even when the sea is calm, yet the outcome is generally good, and most of the patients do remarkably well, even though the operation has been performed in mid-ocean —as our columns have not infrequently testified. When the emergency has arisen in the tropics the cabin is likely to be both ill-ventilated and hot, but still, for the most part this does not seem to have a harmful effect on the patient. It is seldom that any private cabin is sufficiently large to serve for an operating theatre, so, as a rule, the saloon or chief cabin is used. Some of the larger and more modern liners have sections of the vessel which can be devoted to what may be called hospital purposes, but there is seldom sufficient room therein for operating in comfort. Even when the sea is at a dead calm the difficulties of performing a major operation are not small, but they can generally be overcome. If, however, the emergency arises during rough weather the difficulties are enormously increased, and few professional experiences are more exciting, from the terrible responsibility of their nature, than operating for the relief of a strangulated hernia or applying midwifery forceps during a storm at sea. In such circumstances every position is unstable, two or three helpers may be required to keep the patient from sliding about the cabin, and the table or mattress on which the operation is performed will generally need to be lashed in position, so that the patient can be held on it with less difficulty. The surgeon himself may need some assistance in maintaining his equilibrium, and the instruments, lotions, and dressings will need special supervision if they are not to be thrown about with the rolling of the vessel. It is a little wonderful that the results of these operations at sea are so good; the fact speaks clearly for the possession by the surgeon of imperturbability, and of resolution despite distracting circumstances to carry out the essentials of his scientific procedure without hurry or scamping.

In operations undertaken at sea the surgeon has help, unskilful though it may be, and his task would in such troublous conditions be well-nigh impossible if he were deprived of that measure of aid. In some professional situations, however, this degree of assistance is not vouchsafed to the operator, and he is compelled to rely on himself alone. He has to do what needs to be done without any form of help whatever. Where the surgeon has not only to administer the anæsthetic, but to perform the operation, and that single-handed, he is in a very arduous place. Spinal anæsthesia has removed in great part the absolute need for general anæsthetics in operations on the lower half of the body, and the various forms of regional and local anæsthesia also afford aid to the surgeon operating by himself, but all these things bring with them liabilities to error. Many varieties of automatic retractors are now obtainable, and these have relieved the surgeon of the need of an assistant for retracting the edges of the wound. It is probable that most major operations, such as amputations and abdominal sections, can be carried through successfully without any assistance at all, but performances such as these must be regarded rather as *tours de force* than as ordinary efforts of surgical skill. To almost every surgeon occasions will come when he will have to rely on his own unaided efforts, and he will probably obtain better results if he has taken thought beforehand as to what may be expected of him in different junctures. Surgeons are so much in the habit now of relying on a good supply of instruments that many of them are hardly aware with how little it is possible to do all that is necessary. Not that we would undervalue the many forms of instruments which the ingenuity of surgeons and the assiduity of instrument-makers have placed within professional reach, but we may recognise that, when necessary, surgeons can do without them. Should all ordinary surgical instruments be absent a razor or penknife may replace the scalpel, a piece of wire or a hairpin may serve as a probe or a retractor, and an ordinary sewing needle and cotton may supply the sutures. As to skilled assistants, the better the surgeon the more he will value skilled help, for the difference is readily felt when an assistant accustomed to the operator's methods is exchanged for one who is unfamiliar to the special routine. But the emergency of having to operate without help is more easily overcome if preparation has been made for such an eventuality—i.e., if the practitioner, when not oppressed by the imminent call for his services, has thought out for

himself how he would act in certain situations when circumstances had deprived him of his proper instruments and all assistance.

## "Fertility."

THE problems connected with the questions of fertility and fecundity, not only among animals but also in the human race, are exceedingly complex, and our knowledge of the laws governing them is far from perfect. The subject is one of importance, not only to medical men and economists, but also to breeders of animals, and it has not failed to attract the attention of some of the acutest thinkers of the age. It is discussed at length by DARWIN, and HERBERT SPENCER also devoted a considerable amount of attention to the subject. An important fact in relation to the subject is that the birth-rate is falling steadily at the present day, not only in almost all the countries of Europe, but to even a more marked degree in our own colonies. In the Registrar-General's report for the year 1907 an interesting table is given showing, as far as is possible, the comparative fertility of the married women of those countries from which the necessary data can be obtained, and these figures form a valuable measure of human fertility in the several countries. From this table it appears that among the continental countries from which it has been possible to obtain returns there were only two, Austria and Spain, in which the fertility of wives during the 20 years 1881–1901 showed a tendency to increase, and this also applied to Ireland. The fall in the other countries varied from as little as 2·5 and 3·7 per cent. respectively in Italy and Norway to as much as 17·7 per cent. in England and Wales, and nearly 20 per cent. in France and Belgium. In New Zealand and in the States of the Australian Commonwealth the decrease in the legitimate birth-rate was even more striking and ranged from 23·2 to 30·6 per cent. All the evidence available tends to show that while a very small proportion of this decrease may be due to an increase in the age constitution of the married women of conceptive ages, the main part of it must be attributed to a deliberate limitation of child-bearing on the part of the people themselves. The influence of age in diminishing the fertility of married women has had attention drawn to it by MATTHEWS DUNCAN, COGHLAN, and other writers. COGHLAN has shown that the probability of a birth occurring within one year after marriage in the case of a woman aged 21 at the time of her marriage is 396 per 1000, while the probability in the case of a woman married at the age of 36 is only 125 per 1000. In the same way, the effect of age on the average issue is shown by the fact that while the average number of children to a marriage is five when the mother is aged 20 years at the time of her marriage, it is only 1·36 when she is aged 35 and 0·52 when she is aged 40. The average issue of women at the 1901 census married before 1881, when married between the ages of 20–25, was in England and Wales 7·27, while for those married between the ages of 35–40 it was only 1·75; and if recent periods are compared with remote ones there is a definite diminution in the degree of fertility at all ages at the present time.

In considering the factors which influence fertility and fecundity it is necessary to devote our attention to animals rather than to man, because of the fallacies introduced by the prevention of pregnancy among the latter. HERBERT SPENCER put forward the view that the power to sustain individual life and the power to produce new individuals are inversely proportional, so that with an abundant food-supply and a favourable environment there is a high degree of fertility, while with the opposite conditions prevailing the degree of fertility is reduced. There are, however, many other factors which must be taken into account, and one of them, as we have seen, is the influence of age. In this respect, no doubt, the same law applies to animals as to man, and, as MARSHALL points out,[1] GEYELIN has shown that the fertility of the domestic fowl rises to a maximum in the third year after hatching, and in further years gradually falls to a minimum. The marked effect produced by the surroundings and food of an animal upon its fertility was noted in a special way by DARWIN, who attributed the fertility of many of the domestic animals to the regular and abundant food-supply they obtained with a minimum of labour. A very good example of this, cited by him, is the case of the wild duck, which lays perhaps some ten eggs a year, as contrasted with the domestic duck, which may lay as many as 80 or 100 in the course of the year. That good feeding is not the only factor concerned is seen, however, in the case of many wild animals kept in captivity which are often completely sterile in such surroundings even when they couple freely. As DARWIN points out, this condition is common to so many different types of captive animals that it cannot be attributed to any one factor such as change of food, or alteration in the amount of food, or change of climate, or want of exercise. Some further explanation is required, and no doubt it is to be found, as he suggests, in any change in the habits of life which may, when great enough, be found to affect the powers of reproduction. That an excessive amount of food or an improper kind of food may produce such a condition is shown by the notable sterility of animals which have been especially fattened, such as cows which have been fed for the butcher. A similar condition is not infrequently met with in women, and every practitioner is familiar with the young woman who grows rapidly fat and at the same time suffers from complete or partial amenorrhœa and sterility. In this relation the observations of HEAPE and MARSHALL on the conditions which influence the fertility of sheep are of great interest. The former has shown that the fertility of a flock depends largely upon its management, the quantity and quality of the food, the climatic conditions, and the character of the pasture. In an investigation on the fertility of Scottish sheep MARSHALL points out that the practice of "flushing," or the artificial stimulation of the ewes by an extra supply of food at the approach of the breeding season, is undoubtedly beneficial, and the percentage of lambs born is highest among sheep which have been subjected to this process. Not only does this practice tend to increase the fertility of the sheep,

[1] The Physiology of Reproduction, 1910.

but it also hastens the onset of the sexual season, and this result may be ascribed, according to MARSHALL, to a general increase in the ovarian metabolism. At the same time, if the excessive feeding is overdone and the sheep are forced to depend for the rest of the year on a mere sustenance diet, their fertility ultimately tends to become impaired.

Among other factors which must be taken into account in a consideration of fertility and fecundity are the influences produced by in-breeding and by heredity. The inheritance of fertility in man has been investigated by KARL PEARSON, who has demonstrated that fertility is transmitted equally through the male and female parents, while he has also shown in the case of thoroughbred horses that the sire hands down to his daughter a portion of the fertility of his dam. The great importance of the questions to all those who have the welfare of the race at heart was never more apparent than it is at the present day, and these problems will well repay further research, since the volitional limitation of the birth-rate, prevailing as it does chiefly among the more responsible members of society, is associated with no diminution, if not indeed with an actual increase, in the numbers of the mentally and physically unfit. In this connexion we may refer our readers to a striking if unscientific compilation, entitled "Racial Decay," made by Mr. OCTAVIUS CHARLES BEALE, and just published at Sydney, New South Wales.

# Annotations.

"Ne quid nimis."

## STANDARD BREAD.

WE have often enough appealed in our columns for a nutritious loaf of bread, which was also appetising, to replace the dazzling white tasteless rolls and slices which modern machine methods have given us. We have written long since against reducing bread to a mere mass of bleached starch. Nature endows wheat flour with things other than starch, and these things form essential elements in wheat which are of the utmost value to the human animal. We are tired of hearing that "the thing can't be done" when it was done for centuries and centuries before our time, and we are always in some doubt when modern and improved methods are mentioned as to whether the improved method is to the advantage of the consumer. The making of bread has been brought to a remarkably constant standard of recent years, but unfortunately the standard is a poor one, and pays but little compliment to nature's original product. It is based merely on colour, texture, lightness, or any other quality which has no reference to dietetic value at all. Real bread has been taken out of our mouths by modern methods of impoverishment, and it is time to fasten the standard on an altogether different requirement. It is one thing, however, to suggest a standard and another to bring that standard within the range of practical politics. Between the extreme schools let a compromise be made. We are told, on the one hand, that in roller-milled flour certain valuable constituents represented in the germ and the bran are eliminated; those who lay stress on this point seem to forget readily that bread made from such a flour is practically completely absorbed by the eater. On the other hand, while whole-meal contains these valuable constituents its absorption is far from complete, and there is a consequent waste of food material. Physiological experiments have demonstrated these facts, and the husk in the whole-meal is responsible for preventing a certain amount of the bread from being assimilated. The standard bread, it seems to us, should not contain the husk of the wheat, but it should contain the germ, as is the case with stone-ground flour. But the practical baker says of this method of manufacture that the presence of the germ discolours the flour and gives it a decided tendency to become rancid. The germ also contains active diastase which interferes with the production of a satisfactory sponge and dough. If that is the case, it is difficult to understand why very excellent bread with attractive flavour and texture was ever successfully produced in the pre-roller-milling days. We are not prepared to accept the statement that, if the germ offers any difficulty at all, the difficulty cannot be removed. The disadvantages of the presence of the germ in the making of the loaf, if and when they are present, can be overcome and turned into advantages. If we are right here, there can be no question of what the standard for bread should be, though the quality of the wheat must be reckoned with.

## THE HEALTH OF THE ARMY IN 1909.

THE continuous improvement in the health of the British Army that has now been in progress for several years, and to which we are getting accustomed, is more noticeable than ever in the statistics for 1909 which have just been published. We hope to deal with the report in an early issue: at present we merely wish to draw attention to the remarkably high standard of efficiency that has now been reached. The proportionate numbers of men admitted to hospital, and of cases constantly sick in hospital, are practically only half what they were according to the decennial average, 1889–1898; the invalids finally discharged from the service are rather more than half, and the deaths appreciably less than half, the proportionate numbers of that decennium. The improvement has been taking place steadily year by year since the end of the South African war in 1901. It cannot be expected that this progress will be maintained year after year indefinitely—finality must be reached some day; but, as the Director-General intimates, further improvements in the sanitation of barracks and camps, and the advance of preventive medicine, should ensure the maintenance of the present state of health that is so satisfactory. Putting on one side for the moment the professional aspects, whether viewed from the military or the medical standpoint, and considering merely that of the taxpayer, we find that more than 2200 beds in military hospitals at home stations have been closed down as no longer required; while in the colonies a further 901 have been found to be unnecessary. The number of men sent home as invalids has been reduced by 570, compared with the previous year, although the strength of the army is numerically greater. The improvement is manifest in nearly all the preventable diseases that are of importance in military service. Thus, for enteric fever, the admissions were in a ratio of 3·8, compared with 7·2 per 1000 during the previous quinquennium; Malta fever has practically disappeared; venereal affections caused 73·4 admissions, compared with 105 per 1000. Malaria, however, in spite of all efforts at prevention, caused 75·3 per 1000 admissions, a perceptible increase on the decennial average of 64·1, Jamaica, Straits Settlements, and India having suffered severely; though in Mauritius and South China there has been an improvement. Enteric fever is always a source of anxiety to the military medical officer charged with the care of large bodies of men brought together, often under circumstances of urgency; it is gratifying to find that at neither of the large camps at the Curragh or on Salisbury Plain did any outbreak occur during 1909. It is stated that over 80,000 troops were brought together during the summer

on Salisbury Plain under canvas. We have some idea, therefore, of the magnitude of the sanitary problems involved and of the success that attended their solution. Another instance of successful sanitation is that of the territorial camp at Caerwys in Flintshire, where 14,000 men were concentrated; the water-supply had been condemned, and all drinking water was sterilised by means of a heat exchange apparatus with complete success. In India, also, and South Africa there has been a most satisfactory decrease in enteric prevalence. In the former command it is interesting to learn that an increasing number of cases are being reported which show infection by paratyphoid bacilli; in South Africa most of the cases occurred at Pretoria and were of very mild character, such as, in former years before agglutination tests were carried out, would have been returned as simple continued fever or influenza. We notice, by the way, that in this fifty-first volume the title has been changed from "Army Medical Department Report" to "Report on the Health of the Army." If the condition of things during the past year be compared with that existing, say, 30 years ago, there can be no doubt that its description is more fitly styled a report on the health, than on the sickness, of the population concerned. The military authorities generally, and the Director-General and his colleagues in the Army Medical Service in particular, are to be congratulated on the excellent state of the health of the army, which is a source of satisfaction to every citizen of the Empire.

## THE POSITION OF THE GENERAL PRACTITIONER.

A PAPER recently read by Mr. Edward Jessop (President) before the Hampstead Medical Society drew attention to the gradual change which is taking place in methods of treatment of disease and the effect this is having upon the interests and position of the general practitioner. Without containing anything new, Mr. Jessop's views form a good *résumé* of some urgent questions. Whereas formerly treatment mainly consisted in the administration of drugs, new and expensive drugless methods are now replacing the old, and there is a tendency to substitute institutional treatment for treatment in the home, on the ground that the most efficient treatment of disease needs the safeguard and apparatus which are to be had completely only in a hospital or institution, and not in a private house of any kind. The effect of such an opinion, if it become general, will be to deprive the family practitioner of a large part of his practice, at any rate of most of his serious cases. "However much anxiety the present may give the thoughtful practitioner," says Mr. Jessop, "his future is still more precarious, every man's hand is against him; the medical official seems desirous of controlling some ever-expanding portion of the community in order to advance his own sphere of interest, by getting under his own organisation whole masses of the public and pauperising them by offering them free or inefficiently paid medical service." Although we cannot agree entirely with Mr. Jessop in attributing to the rapacity of the medical official the loss which the general practitioner sustains nowadays in many directions, there is much that is true in his complaints and fears. The suggestion of remedies for this state of things is a much more difficult matter than the statement of their many causes. Mr. Jessop finds salvation in professional coöperation in the form of local unionism. As far as the rivalry of out-patient departments goes this form of action is sound. His proposals for the opening and upkeep by the local medical practitioners of a bacteriological and X ray laboratories are novel but not too enterprising for such a district as Hampstead, and would, if carried out, be a practical evidence of local coöperation which it would be pleasant to record. There is a danger, however, of local unionism running to excess and impeding that coöperation between all branches of the profession which the institution of consultative out-patient departments would do much to establish and consolidate.

## ONCHOCERCIASIS.

SINCE the establishment of the Foods Department of the Local Government Board some five or six years ago much admirable work has been done by it in the way of supervision of our foodstuffs and of investigation into the soundness of our meat supplies and the adulteration or sophistication of other articles of diet. The latest contribution furnished by this department deals with a parasitic condition to which the new and strange name of "onchocerciasis" has been given, and which is met with in frozen quarters of beef imported into this country from Australia. The inquiries upon this subject were conducted by Dr. A. W. J. MacFadden, the present Acting Chief Inspector of Foods, in conjunction with Dr. Robert T. Leiper, the well-known helminthologist of the London School of Tropical Medicine.[1] It appears from the reports of these experts that for the last 12 months or more the attention of the department has been directed to the presence of nodular masses, varying in size from that of a pea to that of a walnut, in frozen meat arriving at certain of our English ports from Australia. These nodules, known to butchers and others under various names such as "worm-nests," "white kernels," or "parasitic tumours," contain a thin thread-like worm which Dr. Leiper has identified as belonging to the family Filariidæ, genus Onchocerca, hence the name onchocerciasis. These parasitic nodules are practically confined to the region of the flank and brisket of the forequarter of the animal, though they may occasionally be found in the hindquarter, but in that case limited to a small area over the stifle, or knee-joint. This localisation is of importance, as will be seen, when the meat has to be passed for human consumption or rejected. The condition is not confined to cattle in Australia, but has been found in animals in the United States of America and elsewhere. Happily, the encysted parasitic worms and their young do not survive for more than a few hours the death of the cattle in which they exist. It is interesting to learn that the parasite belongs to a class which needs the intervention of a biting insect in which it has to undergo a portion of its development; without the intervention of this insect the young worms cannot leave their bovine host or enter into the body of another animal. The transmitter or intermediate host of the onchocerca is in all probability either a Stomoxys, Hippobosca, Tabanid, or one of the Ixodidæ. It is very reassuring to hear from the experts that the direct development of the parasite in man as a result of eating the affected meat is *impossible*. From the butcher's point of view the nodules may be regarded as merely interfering with the general appearance of the beef. But the report very properly points out that certain other parasites present in meat foods are of a dangerous and communicable character, and the public are not in a position to differentiate one kind of encysted parasite from another without skilled assistance. It is therefore very undesirable to encourage in the public mind an attitude of indifference towards the presence of any parasitic condition in meat. Although the worms themselves in the beef cannot when eaten by man affect him by producing onchocerciasis in his flesh, yet there can be no

[1] Reports to the Local Government Board by Dr. A. W. J. MacFadden and Dr. Robert T. Leiper, F.Z.S., on a Parasitic Condition (Onchocerciasis) met with in Australian Beef [Food Reports No. 11]. Published by H.M. Stationery Office. Price 6*d*.

question as to classing meat so affected as unsound, for both the worms and the local inflammatory products by which they are surrounded in the nodules are foreign to sound beef and must be objectionable to the consumer. The chief ports at which the affected carcasses are imported are London and Liverpool, and in both of these ports a nearly similar course of action has been, after due consideration, adopted with a view to prevent the use of meat infected by the onchocerca. All forequarters of Australian frozen beef are detained on arrival in cold store until the affected parts —namely, the flanks and briskets—have been sawn off each quarter. The remainder of the forequarter is then released, the flanks and briskets being detained by the sanitary authority in cold store until the importer has given notice that he wishes to dispose of them either for industrial or for food purposes. If it be desired to use the detained parts purely for industrial purposes examination of the meat is not called for; it only remains for the local authority to take the necessary steps, by denaturing or otherwise, to secure that no part of the meat can be used for human consumption. If, on the other hand, the importer wishes to utilise the detained flanks and briskets for food, he is required to have the pieces thawed out and cut up under supervision of an officer of the sanitary authority, who in each case directs on the spot what is to be done should he regard the meat as unfit for food. In the large majority of instances the importers have not availed themselves of the option of having the detained portions examined; they have found it more convenient to surrender the parts in question to the authorities for destruction without examination. This method has necessarily caused financial loss to the importers; but it is to their credit that notwithstanding this they have have shown a ready willingness to comply with the requirements of the sanitary authorities and the central department. The provisions made by the Local Government Board in the Foreign Meat and Unsound Food Regulations, 1908, have enabled the large importations of affected meat to be dealt with efficiently at the port of entry. The extent of these importations may be gathered from the fact that between July and October of last year the port of London alone was receiving between 60,000 and 70,000 quarters of Australian beef per month. The report is reassuring, and shows that we need not be afraid of consuming beef imported from Australia so long as the present method of dealing with it at the port of entry is followed, little if any of the affected meat reaching the market. The report also indicates the value of the work which is being done by the Foods Department and its officers. As the area of distribution of the onchocerca is far wider than Australia we may trust our port sanitary authorities, with the assistance of the Local Government Board and its food inspectors, to maintain a close watch upon all beef carcasses imported from other countries.

## OCCULT PHENOMENA.

THE desire for knowledge which is characteristic of the human intellect has in all ages led men to study the explanation of facts, or rather what appear to be facts. For sometimes the fact turns out not to be a fact. Every one will remember the problem of the fish and the bucket of water which Charles II. propounded to the Royal Society. As an example of an opposite nature, it was evident that the perturbations of the planet Uranus were due to some other body attracting it, and it was suggested that this other body was another and as yet undiscovered planet. This planet, afterwards called Neptune, was assigned a place in the heavens solely by mathematical calculation, and these calculations were carried out independently and practically identically by Adams and Leverrier. Dr. Joseph Grasset of the University of Montpellier, being anxious to record the manifestations of occultism which have been reduced to a scientific basis, has written a book entitled "L'Occultisme Hier et Aujourd'hui; le Merveilleux Prescientifique," and an English translation of this work now lies before us.[1] In Dr. Grasset's words, "Occultism is not a survey of all things hidden from science (I mean to positive science, after Auguste Comte's manner) but which may belong to it." He shows how some occult phenomena have been "redeemed from the domain of occultism," such as hypnotism, the involuntary and unconscious movements which are revealed in table-turning and "the sensation of memory, so-called polygonal." To this last are due crystal visions and the imaginations of mediums. The polygon, we should say, is Dr. Grasset's name for the lower psychical centres. Telepathy and presentiments are phenomena the scientific demonstration of which Dr. Grasset considers at present to be very far off, while mental suggestions and the moving of objects without human contact, such as levitation, are, in his opinion, less difficult to demonstrate and should be at once investigated. We can recommend the work as well worthy the attention of our readers, but if possible they should read it in the original, for M. Tubeuf's English, although wonderfully good for a foreigner, is somewhat difficult to read, as witness the following sentence on p. xxi.: "One takes the risk of being misled because one believes a little in advance, and one hopes that the case, about which one asks oneself if it is true, will prove to be true indeed." There is a danger for some classes of persons that the study of the occult will unbalance a mind which starts in a more or less unstable condition. A study of Dr. Grasset's book will give them a safe chart by which to steer and safe data by which they may, as M. Faguet says in his preface, "calculate the reckoning of the ship." And the limitations and rules laid down will be no less useful to the truly scientific explorer of the borderlands of science as at present known.

## "CHAMPAGNE AND ITS SIMILARS."

IN an annotation last week under the above heading we suggested, when discussing certain fraudulent practices which had been brought to light by the peasants' strike in the Champagne district, that the French Government might do well to inaugurate a system of control, designed to secure the bottling of nothing but the Champagne-grown product under a Champagne label, other designations being reserved for other wines. We now learn that this is exactly what the French Government proposes to do, and a Bill to this effect was placed upon the table of the Chamber of Deputies on Monday last. The Bill provides for a system of State control by which the transport of the wine from the presses of the growers to the cellars of the manufacturers will be under official eyes, and the manufacturers will be bound to store all sparkling wines made from grape-juice produced outside the true Champagne area in cellars which are to remain separate and distinct from the champagne cellars. The cost of this State control is to be met by a tax of five centimes per bottle to be borne by the manufacturer. Finally, a year after the Bill has passed into law wines coming under the definition of champagne will only be allowed to be placed on the market if they bear the word "champagne" in very distinct characters. It is obvious that the measure suggested is calculated to increase the confidence of the consumer, and at the same time the Champagne district will be protected from outside competition and from

[1] The Marvels Beyond Science. By Joseph Grasset, M.D., with a Preface by Emile Faguet of the French Academy; authorised English translation by René Jacques Tubeuf. New York and London: Funk and Wagnalls Company. 1910. Pp. 387. Price 7s. 6d. net.

tactics which were not fair to either. The law may press hard upon the manufacturer in times of shortage; but as the consumer will no doubt be asked to pay for any increase in the cost of production, he may well have his attention drawn to the fact, pointed out by us last week, that champagne "similars," as for example the sparkling saumurs, show dietetic qualities not a whit inferior to genuine champagne. Flavour, after all, may be a costly affair.

## MEDICAL ADMINISTRATION IN TRINIDAD.

IN our issue of Sept. 17th, 1910 (p. 904), we alluded to the proceedings of a commission appointed by the Governor of Trinidad to inquire into the circumstances of an alleged case of plague admitted into the Colonial Hospital and certain statements made concerning the medical administration of the colony. The report of this commission has now been published. It is an exceedingly lengthy document, extending to 146 folio pages, and with the minutes of evidence and appendices forms a volume of 860 pages. The commission sat for 27 days, counsel were engaged on either side, and everything that could possibly be said or written on the matter appears to have been written or said, not once, but many times over. We have, first, an exhaustive report by the chairman, Mr. Justice A. D. Russell; then three separate reports by three of the commissioners; then a joint report by these same four gentlemen; lastly, an independent report by the fifth member of the commission, who, however, agrees in all essentials with his colleagues. We are glad to learn that the commission did not find any of the serious allegations that had been made against the medical administration and personal character of Dr. H. L. Clare, the surgeon-general of the colony, borne out by the facts disclosed in this protracted inquiry. With regard to the alleged suppression of cases of infectious disease the commission does not consider that the surgeon-general acted in bad faith, but finds that his tendency not to recognise such cases became so marked as to expose him to reasonable suspicion of the intention to suppress them, and that owing to the methods he adopted precautions which ought to have been taken were omitted or unduly delayed. As to complaints regarding the cutting down of supplies of drugs and curtailment of the food supplies to hospitals, the commission considers many of these to have been trivial, and that there was no evidence to show that the hospitals had suffered; the surgeon-general's purpose, to ensure economy and check waste, was a good one, whatever may be thought of the means adopted. With regard to the understaffing of the hospitals, it finds that the medical service has been in a dislocated condition, owing to permanent appointments not being made, and that it is a question for hospital experts to decide what an adequate staff for these hospitals should be. It finds that the alterations made in the hospital rules by the surgeon-general were made with good intentions, and, if given a fair trial, might have produced decided improvements. In one instance it was alleged that the surgeon-general, in his capacity of senior consulting surgeon, had neglected his duty in not visiting the hospital to see a case of suspected plague. The commission finds that he was in error in not realising that it was his duty, as well as his right, to visit and advise upon cases, to assist in the diagnosis, and to direct precautionary measures. In recommending the dismissal of a young medical officer in connexion with a supposed case of plague, the commission finds that the surgeon-general acted unjustifiably, and in various respects improperly, especially in keeping back documents which had a bearing on the junior officer's defence, and which it was his duty to forward to the Governor. We are sincerely glad to hear that the chairman of the commission, although not able to acquit Dr. Clare of failings in administrative capacity, finds no proof of any lack of honour or integrity in his character. The other three signatories to the joint report, in their separate addenda, criticise Dr. Clare's action somewhat unfavourably. The lengthy report by the chairman is a careful *résumé* of the circumstances of medical administration in Trinidad during recent years, and includes a psychological study of the surgeon-general, which must be a document of great interest to this officer to read at his leisure, although perhaps not so agreeable for the subject of the study to peruse as for its author to compose. It exhibits an air of philosophic detachment that affords an agreeable contrast to the heated discussions at the court of inquiry. This inquiry was virtually a public trial. Certain letters had been written to the public press of Trinidad by Dr. Fernand de Verteuil, upon which certain charges were based. Counsel appeared for this gentleman, who in the public interest came forward as prosecutor; counsel also appeared for Dr. Clare, the surgeon-general of the colony and responsible medical administrator. The proceedings therefore came to be a forensic battle, each side trying to prove its case, and neither trying to bring out the whole truth. In the course of the contest the surgeon-general was exposed to cross-examination for six whole days; in the words of the chairman of the commission, "over a range of subjects quite unprecedented in my experience." Mr. Justice Russell congratulates Dr. Clare on having come so well out of it, admits that it is a most dangerous ordeal to which to submit an accused man, and apparently would not allow such an occurrence again. We think that the dispassionate form of inquiry, or commission, to which we are accustomed at home, in which the object is simply to get at the facts of the case, not to secure a forensic victory for one side or another, is much to be preferred.

## SEROLOGICAL TESTS FOR BLOOD.

AT a special meeting of the Medico-Legal Society held at the Royal Institute of Public Health on Jan. 25th, Dr. W. R. Smith read a paper giving a *résumé* of the methods employed for the differentiation of human blood stains from those of animals. This was followed by an interesting demonstration of these methods by Mr. L. Rajchman, demonstrator of bacteriology at the institute. The technique of carrying out the precipitin test was demonstrated and explained at length. The principles on which this test is founded are now definitely accepted, and in Prussia, Austria, Würtemberg, and other states the procedure has received official recognition. Unfortunately, the test is a complicated one and can only be satisfactorily carried out by an expert in a well-appointed laboratory. As is well known, the test is based on the fact that if an animal be immunised by injections of a culture of a micro-organism a serum may be obtained from its blood which will cause a precipitate in a filtered broth culture of the same organism. Further, if an animal be injected with the blood of an animal of a different species, there can be obtained from the blood of the injected animal a substance which will produce a precipitate in the serum of the blood of animals of the same species as the animal whose blood was used for injection. For medico-legal purposes, a rabbit is injected with the defibrinated blood of a man, and from the rabbit's blood a serum is obtained which, when dropped into a clear solution of human blood, causes a cloudiness or precipitate to form, a result which is not produced in a solution of blood from another animal. The main difficulty in the process lies in obtaining from the rabbit an anti-human precipitating serum of the required strength. To be thoroughly reliable the reaction (that is, the

formation of the precipitate) must begin in five minutes and be complete in 20 minutes; any cloud appearing after that time cannot be considered as specific. Also, the dilution of the blood to be tested should be 1 in 20,000; more rapid results can be obtained if the dilution is 1 in 1000. Precipitates can be obtained by an anti-human rabbit serum of a less strength if the test is prolonged by incubating the tubes in which the mixed sera are placed, but the results are then found not to be so reliable. It is to be hoped that for purposes of the law opportunities will be afforded by the State for the preparation and further study of the serological tests. The detection and differentiation of blood stains in criminal trials are of such importance that every facility should be officially given for carrying out the necessary laboratory methods. It is an important fact that old blood stains will respond to the test as well as recent ones. Indeed, it seems difficult to fix a limit to the length of time which is required to destroy the substances which produce the reaction. Von Hannmann and Meyer maintain that they have been able to recognise, by means of the precipitin tests, the human origin of mummies 3000–5000 years old. Uhlenhuth and others, however, have not been able to corroborate these observations.

## THE VITAL STATISTICS OF DURHAM COUNTY.

Dr. T. Eustace Hill has been commendably prompt in preparing the vital statistics of the year just closed for the administrative county under his jurisdiction as medical officer of health. We have therefore pleasure in drawing attention to the general improvement he is able to record in the death-rates from most of the chief diseases as compared with the average rates in the decennium 1900–09. In the middle of 1910 the Administrative County of Durham is estimated to have contained a population of 865,960 persons, an increase of 11,160 on the estimated population of the preceding year. In the following table, which is copied from a print issued on the authority of the county medical officer, will be found the vital statistics of 1910, compared with those of the previous year, and also with the average statistics for the years 1900–09:—

| Administrative County of Durham. | Annual rates per 1000 living— | | Mean rates 1900-09. |
|---|---|---|---|
| | 1910. | 1909. | |
| Birth-rate | 34·4 | 35·5 | 35·5 |
| Death-rate (all causes) | 15·1 | 15·7 | 17·5 |
| Zymotic death-rate | 1·62 | 1·61 | 2·20 |
| Infant mortality (per 1000 births) | 126 | 124 | 153 |
| Small-pox | *Nil.* | *Nil.* | 0·007 |
| Scarlet fever | 0·08 | 0·09 | 0·14 |
| Diphtheria and membranous croup | 0·17 | 0·17 | 0·21 |
| Fever (enteric and continued) | 0·09 | 0·12 | 0·17 |
| Measles | 0·20 | 0·37 | 0·39 |
| Whooping-cough | 0·25 | 0·25 | 0·36 |
| Diarrhœa | 0·81 | 0·59 | 0·89 |
| Phthisis | 0·88 | 0·91 | 1·05 |
| Other tuberculous diseases | 0·65 | 0·73 | 0·83 |
| Acute respiratory diseases | 2·42 | 2·38 | 2·94 |

From this table it will be seen that so far from any recovery in the birth-rate there has been a still further fall from 35·5 per 1000 in the ten years ended 1909 to 34·4 in the year 1910. The general death-rate, which in the preceding decennium had averaged 17·5 per 1000 of the estimated population, fell to 15·7 per 1000 in 1909, and further fell to 15·1 in the following year. Infantile mortality last year was in the proportion of 126 per 1000 births, and although this rate was slightly higher than in the previous year it was lower by 27 per 1000 than the average rate in 1900–09. The mortality from tuberculous phthisis, which in the ten-year period ended 1909 was equal to 1·05 per 1000, fell to 0·88 in the year 1910. All the common infectious diseases showed a decline last year as compared with the decennial average; and this decrease is particularly satisfactory in the case of enteric fever, in view of the fact that, according to the Registrar-General's reports, the county of Durham forms part of the northern area of high enteric fever mortality, in which that disease has been exceptionally fatal in recent years. Later on we shall doubtless receive from Dr. Hill the usual more detailed account of the public health in the county of Durham, including particulars of the local distribution not only of mortality but also of the notified cases of enteric fever and other diseases that are known to depend for their propagation mainly on insanitary conditions.

## THE HEALTH OF THE NAVY IN 1909.

WE have received the Statistical Report on the Health of the Royal Navy for 1909, a detailed review of which will be published in a succeeding issue. An outstanding feature of this report is the inclusion in the appendix of papers upon various important medical subjects by surgeons of the service—contributions to professional literature which we welcome with great heartiness. Pyrexia of uncertain origin caused numerous cases of illness in the Mediterranean Command, and we look to the surgeons of the Royal Navy for their share in the elucidation of these diseases. Among noteworthy features are the statistics for venereal diseases, which do not show any diminution in severity nor acceleration of recovery in spite of the improved methods of treatment now available and adopted, and the much-increased prevalence of rheumatic fever in all commands except the Australian. The admission ratio for rheumatic fever compared with the previous five years has been more than doubled, and although some part of the increase has been due to more accurate classification, it is not entirely thus accounted for. The statistics for alcoholism are wonderful—viz., 115 cases in the whole force of 112,700 men. This is a condition of sobriety of which even the most ancient alcohol-immunised nation might be proud, and which reflects the greatest credit upon all concerned, officers and men alike.

## THE DENTAL CURRICULUM.

IN the current issue of the *British Dental Journal* reference is made to the advisability of substituting hospital for private training in dental mechanics. The subject is one on which those intimately connected with the teaching and examining of dental students are deeply interested. In our view systematic instruction at a properly equipped dental school must have a great advantage over training obtained under a private practitioner. It is, perhaps, a pity that our contemporary has not referred more fully to the dental curriculum as at present constituted, for we cannot help feeling that it seems to be out of touch with the modern development of dental surgery. If we go back about 50 years we find that the average dental practitioner was principally occupied with the manufacture of artificial dentures, and that conservative operations, or, to speak perhaps more correctly, dental surgery, occupied but little of his time. We find that the curriculum designed about this period required three years' training in mechanical dentistry and two years' general and dental hospital practice. The practice of dentistry was mechanical rather than surgical. During the "seventies" and

more especially during the "eighties," greater attention was bestowed on conservative operations, and with a corresponding growth in pathological knowledge the practice of dental surgery began to be considerably more surgical, requiring from the practitioner a more thorough knowledge of medicine and surgery. In other words, the practice of dentistry became more the practice of dental surgery than that of dental mechanics. The curriculum, however, demanded by the various examining bodies still continued to insist on three years' mechanical training and two years' general and dental hospital practice. Within the last 20 years, and especially during the last 10, our knowledge of the important relationship between dental and general diseases has made marked progress, dental pathology has made rapid strides, and the practice of dentistry has become more and more surgical in character and less and less mechanical, and there is every indication that the purely surgical aspect will continue to grow. Dentistry, therefore, at the present time demands that the surgical and medical training should be greater than the mechanical. The curriculum, however, has not moved with the gradual evolution of dentistry, for although the Royal College of Surgeons of England has reduced the mechanical training to two years, the time still allotted equals that given to the more important part of the training—namely, the surgical and medical. Without wishing to enter into detailed reasons, it seems to us more in keeping with the actual knowledge required of the dental surgeon that the time allotted to the mechanical training should be reduced and that given over to the medical and surgical training lengthened. In connexion with the general and dental hospital training it does not seem rational that these should be taken concurrently, for it is unwise to try to learn a specialty before the ground principles of medicine have been mastered. The training would be more rational, and without doubt more efficient, if the instruction at the general hospital were completed before the special study of dental diseases is undertaken, and it would be well if the hospital course included instruction in general pathology.

## THE LIABILITY OF AN EDUCATION AUTHORITY FOR ACCIDENTAL INJURY TO A PUPIL.

A CURIOUS case of accidental injury to a child attending a public elementary school at Darnall led recently to an action in the Sheffield county court against the Sheffield Education Authority. The desks used in the school were of a type described as "dividing desks," a portion of which apparently is hinged to the rest and capable of being raised. These had been in use without any recorded accident for 20 years. The plaintiff, a child 6 years of age, managed to insert the tip of the little finger of his left hand in a hole in the hinge of the desk in front of him, and when on the order "to push up desks" being given by the teacher the moveable portion of the desks was raised his finger was caught and injured, a portion of the tip about equal to the length of the nail being torn off. The child was treated at the infirmary, so that no medical attendance had to be paid for, and the evidence did not predict any serious loss of power in the hand; the injury to the finger-tip was disfiguring and the child had suffered pain. The jury awarded £10 damages to the plaintiff against the Education Authority, which presumably implies that they were of opinion that the type of desk used was dangerous, as to which there was evidence that the hole in which the child inserted his finger was not a necessary feature in the hinge. A point of law as to the liability of a local education authority for such an accident occurring in a non-provided school during the hours devoted to secular instruction was argued and was decided by his honour Judge Benson in favour of the plaintiff. Stay of execution was granted when judgment was given in the child's favour so the question as to what may constitute evidence of negligence in a case of this kind, as well as that of the responsibility of the education authority, may be raised again in the Divisional Court. Whatever the final result may be, however, the case shows what extreme care is necessary on the part of school managers to prevent the presence of anything in a school building or playground that is capable of leading to an accident. Certainly no one who has the duty of examining in any capacity the fittings and apparatus used should be reproached with "fussiness" or excess of zeal, because he points out the possibility of an ingenious or careless child being hurt by something which for years has proved harmless to his fellows.

## THE POSITION OF INSPECTORS OF NUISANCES.

SOME additions are made by the new Order of the Local Government Board with regard to public health administration[1] which, while they relate to the duties of the inspector of nuisances, are of great general interest and of far-reaching importance in public health. The inspector of nuisances is now required, if so directed by the council, to remove cases of infectious disease to hospital and to disinfect infected premises. He is also, if so directed, to act as inspector of canal boats and as officer under the Canal Boats Acts, 1877 and 1884. Another duty devolving on the inspector is to furnish annually to the medical officer of health a tabular statement as to the inspections made by him, the number of statutory and other notices served, and the results of such service, data which it is presumably intended should be embodied by the medical officer of health in his annual report. With respect to the work of inspectors of nuisances, the Board takes the view that in places with a population of over 10,000 it is generally desirable that the inspector should devote his whole time to his duties, but in smaller districts the opinion is expressed that the inspector may act as surveyor under the Public Health Act, 1875, as inspector under the Infant Life Protection Act, under the Shop Hours Acts, or the Factory and Workshops Acts, or as assistant officer under the Unsound Food Regulations. He may also act as superintendent of scavenging. All these changes make for the appointment of better qualified and whole-time inspectors, and as such are steps in the right direction.

## TWO RAPID METHODS OF STAINING THE SPIROCHÆTA PALLIDA.

A SUBSTITUTE for the ordinary Giemsa method of staining the spirochæte of syphilis is described by Dr. E. Klausner in the *Berliner Klinische Wochenschrift* of Jan. 23rd. The staining reagent is prepared in the same manner as in the Gram method of staining bacteria. Three cubic centimetres of anilin oil are shaken with 20 cubic centimetres of distilled water for five or ten minutes, and the emulsion so prepared is filtered through a moistened filter-paper. To the clear fluid thus obtained half its volume of a concentrated alcoholic solution of gentian violet is added. The serum or secretion to be investigated is spread out in thin parallel smears along an ordinary microscopic slide and fixed by holding over a 1 per cent. solution of osmic acid for one or two minutes. The gentian violet solution is then poured over the specimen and it is heated for 20 to 30 seconds over a flame. The stain is then washed off with water; the specimen is dried and examined microscopically with an oil immersion lens. The spirochætes are rendered clearly visible by this means, appearing reddish blue against a rose-coloured

[1] THE LANCET, Jan. 21st, p. 175.

ground. The spirochæta refringens is more deeply stained and can be differentiated. Dr. Klausner claims for this method that it is rapid and reliable, that the reagent is easily prepared, and that it will keep for one or two months. He lays great stress upon the strength of the gentian violet, believing that that recommended by him gave the most satisfactory results. Another method is described by Dr. Albert A. W. Ghoreyeb.[1] A smear preparation is made and fixed by exposure to a 1 per cent. aqueous solution of osmic acid for 30 seconds. It is then washed in water and covered for 10 seconds with a solution consisting of liquor plumbi subacetatis diluted 100 times with distilled water. It is again washed and covered for 10 seconds with a 10 per cent. aqueous solution of sodium sulphide. It is then washed and the whole process is repeated twice, the osmic acid solution is then applied for 30 seconds, the specimen is washed in water, dried, and mounted in balsam. Spirochætes, bacteria, and cellular débris are stained black by this method.

## NEW CHEMICAL LABORATORIES AT UNIVERSITY COLLEGE, LONDON.

IN April of last year we brought before our readers an appeal for £70,000 for providing new chemical laboratories at University College, London, including the purchase of a site in Gower-place; and in November we drew attention to the urgency which then existed for the collection before Christmas of £25,000 (the cost of the site) in order that the Senate of the University might be in a position to exercise its option of purchase. By Dec. 10th a sum of £10,000 had been raised towards the required amount, but the total sum was not forthcoming at Christmas. The option to purchase was, however, extended to Jan. 31st, and we are now able to state with much pleasure that the fund has been completed by a generous gift of £4500 from Mr. Ralph C. Foster, and the option on the site has been exercised. Prince Arthur of Connaught now appeals for subscriptions towards the second object, the erection of the building. For this purpose it is estimated that a sum of between £45,000 and £50,000 will be required, and it is hoped that the generous example of all those who have already contributed to the fund for purchasing the site will be followed by other public-spirited citizens so that the cause of scientific research may be advanced in a manner worthy of London. There are cogent reasons why this appeal should find a generous response, for a debt is owed by the public to Sir William Ramsay and his co-workers in the University College laboratories. The application of radio-activity to human needs has become possible largely through their labours and researches, and they are entitled to ask for relief from their present hampered accommodation, in order that they may pursue their labours in adequate and well-equipped laboratories.

IN view of the great practical importance of the newer methods of investigating cardiac disease, especially by the record of the electric changes in the heart with the string galvanometer, the general committee of University College Hospital, London, has established a special cardiographic department, and has placed it in the charge of Dr. Thomas Lewis, whose work in this direction is so well known.

FOUR lectures on Plague (the Gresham Lectures, 1911) will be delivered on Feb. 14th, 15th, 16th, and 17th by Dr. F. M. Sandwith, Gresham Professor of Physic, at the City of London School, Victoria Embankment, E.C. (three minutes' walk from Blackfriars Bridge). The lectures are free to the public, and will begin each evening at 6 o'clock.

THE Hunterian Oration of the Hunterian Society will be delivered at the London Institution, Finsbury-circus, E.C., on Wednesday, Feb. 8th, at 8.30 P.M., by Dr. J. H. Sequeira, on the Progress of Dermatology since Hunter's Time.

PARLIAMENT opened on Tuesday, Jan. 31st, with the election of the Speaker.

# ANNUAL REPORT FOR 1909 OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

## I.

AMONG many important matters discussed in Sir Shirley Murphy's report, upon which we commented briefly in a leading article in THE LANCET of Jan. 14th, attention is once more directed to the difficulty experienced by sanitarians in estimating populations for periods remote from the census. The difficulty is considerable where the area is large, such as that of the County of London. Where the areas are smaller, like those of the metropolitan boroughs, the difficulty is greatly increased, whilst it is well nigh insuperable in the case of foreign cities, concerning which the necessary particulars are seldom available.

*Natural Increase by Excess of Births over Deaths.*

In existing circumstances it is probable that the most reliable measure of vitality will be attained by ascertaining the *natural increase of a population*—i.e., the difference between the births and the deaths occurring in a given period. The *actual increase of a population* cannot be estimated, even approximately, otherwise than by taking account, among other factors, (*a*) of the difference between emigration and immigration, (*b*) of the varying sex and age constitution of the people, and (*c*) of the balance between births and deaths. Consequently, at the present distance from the 1901 census, any estimate of the actual increase of the population must partake of the nature of guesswork. The comparability of separate communities, as regards the natural increase of their populations, is sometimes affected by migration. It may also be affected even more seriously by differences in the age and sex constitution of the living. Nevertheless, the combined effect of these disturbing agencies can hardly suffice to vitiate general comparison of the crude rates of natural increase as among separate communities.

From a table exhibiting the local rates of natural increase it appears (1) that in all the largest English towns except Hull the rate of increase in 1909 was below that of the preceding five years, and (2) that in the same year the rate exceeded that of London in six of these towns, and was below it in seven others. From another table comparing the rate of increase in London with that of the chief foreign cities we learn that the rate was above that of London in Amsterdam, Copenhagen, and New York, but below it in seven other cities—the lowest rate obtaining in Paris, where it was only 0·3 per 1000. We further learn that in 1909 the excess of births over deaths was below the quinquennial average in all the chief foreign cities except Copenhagen, St. Petersburg, and New York. With reference to this table Sir Shirley Murphy remarks that where the populations concerned are of different nationality the factors affecting the rate of natural increase tend to vitiate comparison even more seriously.

*Continued Fall of the London Marriage-rate.*

Concerning the proportion of marriages among Londoners the county medical officer remarks that in the year under notice it was only 15·8 per 1000 living—a rate which is not only the lowest on record, but is below the mean rate in 1851–60 by 4·8 per 1000. Throughout the closing 30 years of the last and the first nine years of the current century there has been an almost uninterrupted decline in the London marriage-rate. For many past years the proportion

of minors in 100 marriages at all ages has been diminishing steadily. In the year under review 3·1 per cent. of the husbands and 11·1 per cent. of the wives were under the age of 21 years, the percentages in the decennium ended 1890 having been 18·9 and 20·8 respectively. Calculated on the total number of marriageable persons—i.e., on the unmarried and widowed portions of the community aged 15 years and upwards—the London marriage-rate has declined during the last 37 years by not less than 27 per cent.

*Decline in the London Birth-rate.*

The decrease in the birth-rate of the metropolis noticed in previous reports has continued through the year 1909, when the proportion did not exceed 24·2 per 1000 living at all ages; this is the lowest rate recorded since the establishment of civil registration, and is lower by 11·2 per 1000 than the rate in 1861–80, in which decennium the birth-rate attained its highest point. In this connexion Sir Shirley Murphy quotes a recent statement by the Registrar-General to the effect that as compared with 1870–72 the London birth-rate in 1909, calculated on the female population aged 15–45 years, has declined by 34·0 per cent. By means of another table the birth-rates of London are compared with those of other large English towns and cities. In the calculation of rates for this table the births in the principal lying-in institutions have been referred to the districts from which the mothers originally came. Another table is presented showing the rates of legitimate births in each metropolitan sanitary area in every 100 married females between the ages of 15 and 45 years. From this table it appears that the legitimate birth-rate ranges from 13·1 per cent. in Hampstead and 14·7 per cent. in Holborn, to 24·7 per cent. in Bethnal Green and 25·5 per cent. in Bermondsey. In another table the London birth-rate is compared with that of other large English towns, and from this it appears that in the year under notice the London rate was exceeded in nine out o 13 of the chief English towns, the remaining four alone showing rates below that of London. In contrasting the decrease of birth-rate in the different towns it is necessary to bear in mind that the value of these rates depends on the accuracy of the population estimates, which may, and probably does, vary considerably. In yet another table it will be seen that the decrease in the birth-rate which still persists in England and Wales is shared by all the principal foreign capitals, and that the birth-rate of London still compares not unfavourably with that of the majority of those capitals.

*Relation of Fertility to Social Condition.*

With respect to the standard adopted for the purpose of grouping sanitary districts in order of social condition the following facts are important. In tables going back to 1901, or in tables published in previous reports, the grouping of London districts in five groups of differing social condition has been based on the percentage of persons living in overcrowded tenements of less than five rooms, as shown by the latest census returns. But in tables appearing for the first time in the present report, or in tables dealing with figures for recent years only, the grouping is based on the proportion of children aged from 5 years to 14, scheduled for education purposes in the schools of the County Council. According to the latter classification we observe that Group I. consists of districts where the proportion of children scheduled for education purposes is less than 79 per cent., Group II. from 79 to 85 per cent., Group III. from 85 to 91 per cent., Group IV. from 91 to 97 per cent., and Group V. where the proportion exceeds 97 per cent. In this connexion, however, it is important to realise the fact that the proportion of children thus scheduled can only be ascertained by relying on an estimated total of children at school ages in each borough, and that these estimates are based upon the population of 1907 calculated for purposes of rate equalisation. Consequently, if there has been a movement of population limited to persons of one social grade it is obvious that the resulting comparisons will be to some extent affected. It is common knowledge that the fertility of married women decreases with advancing age; accordingly a comparison of the fertility rates of different sections of a community will be affected to a considerable extent by differences in the age constitution of married women in each community. Among married women in the poorer metropolitan districts the percentages living at the younger ages are higher than in the districts of a better class. With the object of correcting as far as possible for these differences, a factor has been calculated, based upon observations made in Sweden during the period 1891–1900, of the number of accouchements at certain ages among married women between the ages of 15 years and 45. No similar figures for the United Kingdom are available for recent years, but the Swedish figures do not differ materially from those relating to Edinburgh and Glasgow for the year 1855. From a table showing the results of applying this correcting factor to the London figures for 1903–09 we gather that if the fertility-rate of the metropolis as a whole, corrected as here indicated, be taken as 1000, the corrected rate will range from 873 in the first or best group of districts, and 914 in the second group, to 1112 in the fourth group, and 1264 in the fifth or worst group.

*Compulsory Notification of Births.*

In October, 1909, the Local Government Board, at the instigation of the County Council, made an order declaring the Notification of Births Act to be in force throughout the metropolis, eight of the metropolitan borough councils having refused or neglected to voluntarily adopt the Act. Under the Board's order the County Council now receives intimation of the whole of the births notified in London to the borough medical officers of health. Comparison of the number of births notified under the recent Act, with the number registered under the Act of 1874, reveals the fact that in some boroughs the requirements of the Births Notification Act have not as yet been fully complied with, notwithstanding the efforts of the sanitary authorities to make those requirements known. In Southwark and Finsbury the number of births notified slightly exceeds the number registered; this is due to the circumstance that the average interval between birth and registration is considerably longer than the interval between birth and notification. In several of the metropolitan boroughs the excess of registered over notified births is noteworthy.

*London Mortality in 1909.*

In consequence of favourable meteorological conditions and of comparative freedom from excessive epidemic prevalence the mortality of London continued to be very low in the year under review. Corrected for age and sex constitution of the population, the rate was only 14·7 per 1000 of the living at all ages—a rate which, although higher than that of the preceding year, was lower by 1 per 1000 than the mean rate in the five years 1904–8. The rate of London was lower than that of any other great English town, except Bristol and Leicester, and was also lower than that of any of the chief foreign cities, except Brussels and Amsterdam.

Among the metropolitan sanitary districts the corrected death-rates continue to show the usual wide variation. Thus, in the year under notice, whilst the rate did not exceed 10·1 per 1000 in Hampstead and 10·8 in Lewisham, it rose to 20 per 1000 in Shoreditch and 22·3 in the City of London. In this series of reports the death-rates of the London sanitary areas are fully corrected for institutional mortality. In the text of the present report attention is again drawn to the circumstance that in calculating the rates of mortality the populations have been estimated on the assumption that the rate of increase observed in the last intercensal period has since been maintained. The validity of this assumption may well be questioned, especially in view of the fact that a period of eight years has elapsed since 1901, the date of the last census enumeration. Moreover, we must remember that emigration and the declining birth-rate of recent years, besides affecting the numbers of the population, have probably altered its age constitution, in many instances considerably, and it is obvious that for this disturbing agency no reliable correction can be made until the figures of the forthcoming Census are available.

The statistics already discussed in this article relate to the mortality at all ages; but the report contains additional tables in which the rates of mortality at several stages of life are compared with corresponding data in the preceding decennium. From one of these tables we gather that in the year under notice the rate of mortality at each age period of both sexes was considerably lower than the average in the preceding decennium, except at ages above 65 for men and at ages above 85 for women.

*Saving of Life Expressed in Terms of "Life-Capital."*

Sir Shirley Murphy again draws attention to the fact, emphasised in several of his previous reports, that a more accurate estimate than the foregoing of the effect on the community of fluctuations in mortality can be obtained by the use of a life-table. The advantages of that method with the formulæ employed in its application are set forth in detail in the London life-table appended to the report for 1901. From instructions contained in that document it appears that in order to apply this method it is necessary in the first place to ascertain from the life table the mean future lifetime of males and females in groups of ages corresponding to the age groups in which the deaths appear. With the help of the life-table for 1891–1900 this has been done for the purposes of the present report, which contains a table showing the mean future lifetime, or expectation of life, of males and females respectively at several groups of ages. Incidentally we observe that in London the expectation of life at birth amounts to rather more than 50 years for males and to nearly 54 years for females. In a further table the number of deaths occurring in the year 1909 is compared with the number that would have occurred had the death-rates of 1891–1900 been maintained in 1909. The number of lives gained in the latter period is also shown, and this gain is expressed in terms of "life-capital," which is obtained by applying the mean future lifetime to the number of lives saved at each group of ages. From this table we learn that in the year 1909, compared with the decennium 1891–1900 there has been a saving of 24,902 lives, representing a gain to the community of 1,080,784 years of "life-capital."

*(To be continued.)*

## ROYAL SOCIETY OF MEDICINE.

A SPECIAL general meeting of Fellows of the Royal Society of Medicine was held at Steinway Hall, London, W., on Jan. 31st, when Sir HENRY MORRIS, the President, occupied the chair. The business before the meeting was the consideration of a communication from the council of the society to the Fellows in regard to the new premises of the society, to which it was proposed to add one storey.

A memorandum on the society's new premises signed by Sir Henry Morris pointed out that on Oct. 28th, 1910, the council of the Royal Society of Medicine entered into a contract with Messrs. Godson and Sons for the erection of a building of three storeys—i.e., ground-floor and first and second floors—at a cost of £27,286. This building included ample meeting room and sufficient library accommodation to last for many years—indeed, for as long as the present lease. The question of a third and a fourth floor was left undecided, but the council reserved the right to order an additional or third floor, according to the approved plans, and at a fixed price (£2051), and also the right at a later date to order another or fourth floor, according to plans approved, at a price fixed (viz., £2347)—that is, at a total cost of £4398 for the two additional floors. When the contract was signed the council did not feel justified in incurring more expense than was absolutely necessary for the immediate needs of the society. They hoped that before the limit of time fixed for the notice to be given for a third floor had arrived they might see their way to order an additional floor or floors, if thought advisable. A third floor would provide a more spacious common room for the use of Fellows, a room in which to conduct the examination of morbid growths and other specimens, a room for the use of the president and presidents of sections, a secretaries' room (including writing and conference conveniences for the sectional secretaries), and a Fellows' smoking-room. Some or all of these rooms would also, when required, provide additional storage for books. These rooms were all desirable for the full and satisfactory working of the society from the outset, and should be provided if possible. If the notice to erect the third floor was given on or before Feb. 7th the cost would be £2051. If the additional floor was not built now, and the Fellowship of the society increased and new sections were formed, it would certainly become necessary within a few years. The cost would then be at least £4000, and the building operations would necessitate the closing of the society's house for nine months or longer. The council were of opinion that the erection of the third floor was desirable, but they sought to ascertain the opinion of the Fellows before giving notice to the architect, as they must do, on or before Feb. 7th, if the work was to be carried out. The total cost of the building would then be under £30,000. The building fund at present stood at a total of between £10,000 and £11,000, made up as follows: Donations and subscriptions already received, £6725 16*s.*; donations and subscriptions promised, £2519 18*s.*; debentures surrendered, £1450. As only 678 Fellows and members had contributed to that amount, the council appealed to each of the remaining 2700 to help, by subscribing a sum of from 1 to 5 guineas annually for three or five years. In this way a large portion of the balance required might be provided before the building was finished. It should be remembered that before the amalgamation many Fellows belonged to several societies, and paid in annual subscriptions—few less than £5 5*s.*, many as much as £10 10*s.*, and even more. As these Fellows now obtained much greater advantages for a subscription of £3 3*s.*, it was hoped that they would make a special effort, in the manner suggested or in some other way, to bring up the building fund to the requisite amount.

Sir HENRY MORRIS said that the memorandum which had been circulated contained a full account of the whole matter. He particularly emphasised the fact that the proposal was a financially sound one, and went on to assure the Fellows that there was not the slightest intention of the new premises being used in any way as a club-house. On the contrary, the whole of the building would be used strictly and entirely for scientific purposes.

Sir THOMAS BARLOW, President of the Royal College of Physicians of London, then submitted a motion confirming the resolution of the council as to the desirability of building an additional storey, and he pointed out that in his opinion the plan commended itself as business-like and as dealing with the pressing needs of the society in a satisfactory manner. He was sure he expressed the sentiments of a large number of Fellows in stating his satisfaction at hearing that in the new building every part of it would be used for the needs of the society itself, and that the premises would not in any way constitute a club-house.

Mr. BUTLIN, President of the Royal College of Surgeons of England, in seconding the proposal, said that it would be absolutely ridiculous on the part of the society to hesitate to face the financial liability incurred in building the additional storey.

Mr. G. H. MAKINS and Dr. C. THEODORE WILLIAMS supported the motion, and Dr. W. HALE WHITE was instrumental in the secretary of the society demonstrating to the Fellows on a large plan the particular storey concerning which the motion was put forward.

After Sir WILLIAM CHURCH had explained, in reply to some remarks of Mr. L A. BIDWELL, that the necessity for establishing the present financial arrangements of the society was to be found in the need of financing the society on an annual subscription of 3 guineas from each Fellow, the resolution proposed by Sir Thomas Barlow was duly voted for and carried *nem. con.*

## PUBLIC HEALTH IN THE STRAITS SETTLEMENTS.

THE report on the medical department of the Straits Settlements for 1909 is somewhat late in its appearance; but this is not at all to be wondered at when we consider how extremely scattered is the collection of districts or provinces to which it refers. The principal medical officer, Dr. W. Gilmore Ellis, has his headquarters at Singapore, and presents his report in the form of a very short condensation of the various provincial reports, which are given *in extenso* in a series of appendices. The total population was estimated at 636,691, the birth-rate being 26·69, and the death-rate 37·58 per 1000; it is stated that the birth-rate has declined in all the settlements, also that the death-rate was the lowest since 1899. No comparative statistics are given relating to previous series of years; perhaps they are not available, owing to changes in the areas and populations of these provinces. The four "settlements" constituting the colony are, or rather were, at the beginning of 1909—(1) the island of Singapore; (2) the island of Penang; opposite which, on

the mainland of Malacca, are (3) Province Wellesley, and further south the district of the Dindings; further south again (4) Malacca, the largest of the settlements. The island of Labuan, off the north-west coast of Borneo, is also included in the administration of the colony.

*Vital Statistics.*

Of the zymotic diseases, cholera caused 76 deaths (out of 84 cases), all in Singapore; of plague there were but 5 cases (all fatal), also at Singapore; of small-pox, 62 cases and 11 deaths. Of enteric fever there were 235 cases and 89 deaths in Singapore, a smaller number than in either of the two years preceding; but it is stated that the figures cannot be relied on, as many cases are probably included under "fever unspecified." Beri-beri caused 873 deaths in Singapore, a markedly smaller number than in 1907 or 1908; in Malacca there were 219 deaths, and in Penang 399 deaths, neither of these figures showing much improvement. Phthisis prevails to a considerable extent, having caused 2659 deaths, a lower figure, however, than in the two years preceding. Dr. Ellis considers that this high mortality is likely to continue until some practical measures are put in force in the large towns to lessen overcrowding, improve ventilation, and remove advanced cases. Malaria is credited with 2589 deaths, of which 1670 occurred in Singapore; but it is admitted that the figures are quite unreliable. It is not possible to form any satisfactory opinion as to the condition and progress of the public health from the figures presented in this report, as mere numbers give no intelligible idea unless expressed as a ratio to the population. Perhaps the information is not available for any long series of years on account of the changes that have taken place in the areas and populations of these provinces. We do not understand, however, why no ratios are given for the older settlements, such as Singapore and Malacca, the populations of which are presumably known with some degree of accuracy. No information is given as to race or nationality in any of the returns, except those relating to lunatic asylums; this materially detracts from their interest.

The health statistics of the Singapore jail were satisfactory. No case of beri-beri originated in the prison; this in the third year in succession in which this immunity has occurred; the total death-rate was 28·3 per 1000. In the municipality generally the rate was 38·56, showing a considerable improvement on the mortality ratio for 1908, when it was 46·78. In Penang Island the chief causes of death were phthisis, malaria, fever, and beri-beri; 901 deaths occurred from phthisis, rather fewer than in 1908, when there were 917, but more than in any of the four years preceding; the highest mortality previously having been 674 in 1906; no explanation is given of this great increase within the last two years. Malaria also was less fatal (712 deaths) than in 1908, when there were 820 deaths, but more severe than in any of the four years preceding; no explanation is suggested for this. The next most fatal disease was fever of unspecified nature, accounting for 432 deaths; under this heading there has been a continuous improvement since 1904, when the mortality amounted to 1111; we suppose more cases have been returned as "malarial" in recent years. Some anti-malarial operations have been undertaken in the way of filling in ditches and low-lying areas of land, draining ponds, oiling ponds, and extending the drainage system. Two deaths occurred from small-pox: one was that of a European lady landed from Rangoon at the quarantine camp; she was suffering from hæmorrhagic small-pox in a malignant form, and bore no marks of vaccination. Dr. J. Kirk, reporting on the ophthalmic work at the Penang District Hospital, again alludes to the large number of cases of trachoma treated, 38 in all; he considers it to be responsible for 80 per cent. of the eye trouble and blindness which exist in the station. Mr. D. M. Ford was in charge of the leper asylum at Pulau Jerejak; the average number of inmates was 396, the largest ever recorded. Whether this was due to spread of the disease or increased stringency in sending patients to the asylum we are not informed; no explanation is offered of this, on the face of it, important fact, which would appear to be disquieting and worthy of notice. The health of Wellesley province is reported by Dr. W. S. Sheppard to have been fairly good in 1909; there was no serious epidemic. On some estates in the south, however, there has been a prevalence of dysentery greater than in former years. The food- and water-supplies have received attention, and the only cause Dr. Sheppard can suggest is adulterated toddy; it is frequently only the adult Tamils that suffer, while Javanese and Chinese escape. The death-rate for Malacca province was 41·46 per 1000, practically the same as the birth-rate, which was 41 03; in the previous year the death-rate was even higher, 47·88; of the deaths, more than half were due to fever, malarial or other; and 30 per cent. were in children under one year, 1036 being due to convulsions. The bulk of the population consists of Chinese and Malays. Beri-beri caused 52 deaths; it is stated that parboiled rice is now used in the various Government institutions. One fatal case occurred at a police depôt; the victim, a sub-inspector, had been warned against Siam rice, but refused to alter his diet.

*Various Matters.*

As regards general sanitation we are not afforded much information. The question of sewage disposal in Singapore is not yet finally settled; an expert from home was called in during the year, and his report is now under consideration. Of nine samples of water analysed from Singapore, one was found to be highly contaminated by sewage and five consisted "for the most part of oxidized sewage."

There is a Government medical school at Singapore, giving the full curriculum for the Licence in Medicine and Surgery, attended by 72 full course students, mostly Tamils and Chinese; the results of the examination were satisfactory, except in the subject of pharmacy, for which a new lectureship has now been established. Graceful acknowledgment is made to Major E. M. Pilcher, R.A.M.C., and Dr. G. A. Finlayson for their enthusiasm and thoroughness in teaching clinical surgery and medicine.

The meteorological statistics supplied are meagre, inasmuch as they do not give any information whatever as to the normal conditions, as deduced from a series of years; neither is anything said as to the localities where observations are taken. Singapore had a rainfall of 110 inches and a mean temperature of 82·4°; at Penang the rainfall was 130 inches and the mean temperature 81·7°. For Province Wellesley, that is presumably Georgetown, 220 inches of rain were registered, and a mean temperature of 83·3°. Malacca had a rainfall of 87 inches and a mean temperature of 81·3°. Labuan is out of the zone of high rainfall, and had only 9·5 inches, with a mean temperature of 83·4°.

The preparation of this report has entailed great labour, and we are appreciative of the large amount of information conveyed in small space. Some attempt at generalisation and advancing the boundaries of knowledge in regard to tropical pathology in these somewhat remote regions would have been welcomed. We are surprised that no mention is made of the large addition of territory that took place in the early part of the year to which this report refers; an area of some 15,000 square miles, with a population of about half a million, was transferred by Siam to the British Government, a circumstance, we should have thought, that would have given occasion for some action and report on the part of the public health authorities of the colony.

## ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on Jan. 26th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The following gentlemen having passed the required examination were admitted Members of the College: John Hay Burgess, M.D. Lond., L.R.C.P. (Captain I.M.S.), Lancelot Stephen Topham Burrell, M.B. Cantab., L.R.C.P., Frank Clayton, M.B. Cantab., L.R.C.P., David McCay, M.B. Roy. Univ. Irel. (Captain I.M.S.), Bidhan Chandra Roy, M.D. Calcutta, L.R.C.P., and Ernest Edwin Waters, M.D. Edin. (Major I.M.S.).

Seventy-five gentlemen who had passed the requisite examinations were granted licences to practise medicine.

Diplomas in Public Health were granted jointly with the Royal College of Surgeons of England to the following:—Scott Campbell Adam, Claude John Eddowes Bennett, Harold Boulton (Major I.M.S.), Herbert Maughan Brown, Percy Norman Cave, Roderic Arthur Clapham, Alexander Dawson (Captain R.A.M.C.), Kali Charan Dube, John Henry Jones, Charlotte Alice King (under the Medical Act, 1876), James Fitz-Gerald Martin (Captain R.A.M.C.),

Lawrence Pick, Arthur Meurig Pryce, Thomas Edwin Pryce, Norman Emil Henry Scott (Captain I.M.S.), Sidney Francis St. Germain Steadman, Sidney John Steward, Charles Henry Straton (Captain R.A.M.C.), May Thomson (under the Medical Act, 1876), Sydney Arthur Tucker, and Charles Wilfred Vining.

The following communications were received: 1. From the Secretary of the Royal College of Surgeons of England, reporting proceedings of the Council of that College on Dec. 8th and Jan. 12th last. 2. From the Director-General of the Medical Department of the Navy, reporting that Sir Gilbert Blane's medals had been awarded to the following officers: Fleet-Surgeon G. T. Collingwood, M.V.O., and Fleet-Surgeon A. R. Bankart, M.V.O. 3. From the Assistant Secretary to the Marine Department, Board of Trade, inviting the College to nominate a representative on a committee for revising the scales of medicines, &c., for merchant ships. The President nominated Dr. N. I. C. Tirard. 4. From the Registrar-General, concerning the substitution of the International List of Causes of Death for the list hitherto in use at the General Register Office. 5. From Mr. Alfred Parsons, asking permission to have a reproduction made of the late Dr. J. F. Payne's portrait. The request was granted. 6. From Professor Osler, on behalf of Dr. Harvey Cushing, asking permission to have the portrait of Vesalius photographed. This request was also granted. 7. From the University of St. Andrews, inviting the College to send a delegate to the celebration of the 500th anniversary of the University in September next. The President was requested and consented to represent the College. 8. From the Royal Sanitary Institute, inviting the College to send a delegate to its Congress at Belfast in July next. The Right Hon. Lord Ilkeston was nominated. 9. From the British Medical Association, concerning diseases of the eye as a compulsory subject for the curriculum and examination. The matter was referred to the Committee of Management.

The PRESIDENT announced that he had nominated Dr. C. Theodore Williams as Harveian Orator, and Dr. Graham Steell as Bradshaw Lecturer for 1911; also, that the Council had appointed Dr. F. A. Bainbridge as Milroy Lecturer for 1912.

The Right Hon. Lord Ilkeston, Sir H. Bryan Donkin, Dr. R. Caton, and Dr. J. Phillips were elected councillors.

Sir Dyce Duckworth was re-elected a representative of the College on the council of Queen Victoria's Jubilee Institute for Nurses.

Sir Francis Champneys was appointed a representative on the Central Midwives Board for one year from April 1st next.

A report was received and adopted from the representative of the College on the General Medical Council on the proceedings of the Council during its session in November last.

After some further business, the PRESIDENT dissolved the Comitia.

---

DONATIONS AND BEQUESTS.—The late Mrs. Sarah Jenkins, of Edgbaston, Birmingham, has among other bequests left by will £500 each to the Royal Orthopædic and Spinal Hospital, Birmingham, and the Birmingham and Midland Free Hospital for Sick Children; £350 to the Birmingham and Midland Skin and Urinary Hospital; £250 each to the Birmingham General Hospital, the Queen's Hospital, Birmingham, the Birmingham and Midland Hospital for Women, the Birmingham Lying-in Charity and Maternity Hospital, the Birmingham and Midland Counties Sanatorium, Blackwell, Worcestershire, and the Birmingham and Midland Eye Hospital; £200 each to the Birmingham Branch of the Royal Society for the Prevention of Cruelty to Animals, the Birmingham District Nursing Society, the Moseley Hill Convalescent Home for Children, near Birmingham, Dr. Barnardo's Homes (Birmingham Branch), and the Dental Hospital, Birmingham; and £150 each to the Birmingham Branch of the Royal Institution for the Instruction of Deaf and Dumb Children, and the General Institution for the Blind, Edgbaston.—The late Miss Hampson of Radcliffe has left £1000 to the Manchester Royal Infirmary, £1000 to the Bury Infirmary, £1000 to the Southport Infirmary, £1000 to the Pendlebury Hospital for Children, and £1000 to the Trustees of the Radcliffe and Whitefield Relief Fund for Consumptives, besides other charitable bequests.—The late Miss C. C. Williams of Falmouth has bequeathed £6000 to the Royal Cornwall Infirmary.

# Public Health.

## ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Report of the Health Officer of Calcutta for the Year 1909.*—Dr. T. F. Pearse, health officer to the corporation and special health officer for plague, Calcutta, in his report for 1909 follows his usual mode of procedure, noticing in detail the meteorological data, the vital statistics, and the special diseases occurring during the year. He gives an interesting account of an outbreak of beri-beri or epidemic dropsy. It is now our pleasure to review the interesting facts he has collected. Dr. Pearse in his report for 1908 drew attention to the fact that the climate was on the whole cooler and drier than usual, the lessened humidity being a special feature. Concurrently with these meteorological conditions the year was an exceptionally healthy one, the estimated mortality being lower than for ten years previously. But in 1909 the meteorological conditions were different. The earlier part of the year was hotter and drier than usual, and the rainfall exceptionally small, but during the second quarter the humidity and rainfall were in excess. During the latter part of the year the humidity was of about the average, so that generally the humidity was distinctly higher and the atmospheric conditions not so favourable. The health officer points out that the vital statistics are entirely dependent upon the accuracy of the registration of deaths and upon the corrections made after inquiry into the cause of deaths as given at the several burning ghats and burial grounds. That these corrections are important is shown by the experience that nearly 50 per cent. corrections have to be made in the returns as given by the latter. Inasmuch as the causes of deaths are dependent upon the haphazard opinion of the individuals who happen to register each death, Dr. Pearse very rightly protests against any attempt to reduce his present small staff, as such reduction would inevitably be followed by a vitiation of the statistics which would render them practically worthless. He does not hesitate to say that the mortality returns before the year 1903 are of little value. The total number of deaths during 1909 was higher than in the previous year, but the increase was chiefly due to the larger mortality for small-pox, plague, and epidemic dropsy. Excluding these, the general mortality was in fact lower. The "crude" rate, moreover, is not really the correct one, since no allowance was made for the increase of population as regards the excess of males, of young adults, and the comparative paucity of children. The death-rate may in reality be taken as 28·7 per 1000, and is only slightly higher than in 1908. It compares favourably with that of Bombay, 35·5 per 1000. There was an excess of deaths amongst the females in every part of the city, in every district as well as in every ward. Bowel complaints gave a marked improvement, due no doubt to the recent drainage operations. These latter diseases were nearly double in the suburbs compared with the city. Malaria gave a lower mortality during the wet season. The cholera death-rate was 2·3 per 1000; that for small-pox 4·4 per 1000. This disease showed a severe outbreak in the spring of 1909; the severity is shown by the contrast with the mortality rate of the previous five years—viz., 1·2 per 1000. Vaccination was consequently performed to a much greater extent, 88,306 operations having been performed. An extremely interesting section of the report deals with an outbreak of beri-beri or epidemic dropsy. Dr. Pearse, as is well known, has strongly advocated the identity of these two diseases, and has adduced potent arguments in favour of his theory. In the account of the epidemic he details the symptoms, and draws attention amongst other points to the mode by which death is brought about—namely, by nervous disturbance of the heart's action. He also ably discusses the question as to the identity or non-identity of the two affections, and finally considers its causation, whether it be caused by some adulterant or poison contained in the food, or whether it is an acute specific communicable disease. His own opinion favours the latter supposition. With respect to malaria, the Calcutta corporation sanctioned the appointment of ten mosquito brigades for six months. Work was started with these on Oct. 1st. A large amount of work was effected with regard to the bacteriological examination of the Hoogli river water, of the filtered water-supply, and the analysis of foodstuffs. Many other points are mentioned in this

valuable report which space only forbids us to relate. It concludes with tabulated statements relative to the climate of Calcutta, death statistics, and deaths from various diseases. Dr. Pearse has produced as usual a most valuable exposition of the matters connected with his department.

# VITAL STATISTICS.

## HEALTH OF ENGLISH TOWNS.

In 77 of the largest English towns 8232 births and 5310 deaths were registered during the week ending Jan. 28th. The annual rate of mortality in these towns, which had been equal to 14·3, 15·5, and 16·4 per 1000 in the three preceding weeks, declined to 16·1 in the week under notice. During the first four weeks of the current quarter the recorded death-rate in these towns averaged 15·6 per 1000. In London the mean death-rate during the same period was equal to 15·7 per 1000. The annual death-rates in the 77 towns during last week ranged from 6·8 in Hastings, 7·4 in East Ham, 8·4 in Handsworth, and 8·5 in Walthamstow and in Burton-on-Trent. The 5310 deaths from all causes in the 77 towns last week showed a decline of 101 from the number returned in the previous week, and included 461 which were referred to the principal epidemic diseases, against 392, 448, and 455 in the three preceding weeks; of these 461 deaths from epidemic diseases, 208 resulted from measles, 113 from whooping-cough, 58 (of infants under two years of age) from diarrhœa, 48 from diphtheria, 17 from enteric fever, and 17 from scarlet fever, but not one from small-pox. The fatal cases of measles, which had increased in the three preceding weeks from 160 to 204, further rose last week to 208, and caused the highest annual rates, 1·9 in Coventry, 2·6 in Bury, 2·8 in Grimsby, 2·9 in Sheffield, and 4·6 in Rotherham. The 113 deaths from whooping-cough also showed a further increase upon recent weekly numbers; the highest rates from this disease last week were 1·6 in Croydon, and 2·1 both in Norwich and in Warrington. The deaths of infants under two years of age attributed to diarrhœa and enteritis, which had been 56 and 68 in the two previous weeks, declined again last week to 58. The fatal cases of diphtheria, which had been 63 in each of the two previous weeks, declined last week to 48, of which 12 occurred in London and its suburban districts, 6 in Liverpool, 3 in Manchester and Salford, and 3 in Leeds. The 17 deaths referred to enteric fever exceeded the number in the previous week by 2; 5 were recorded in London, 3 in Manchester, and 3 in Bradford. The fatal cases of scarlet fever, which had been 31 and 20 in the two preceding weeks, further declined to 17 last week; 3 occurred both in London and in Liverpool, and 2 each in Portsmouth and in Cardiff. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily declined in the 11 preceding weeks from 1882 to 1349, had further fallen to 1311 on Saturday last; 129 new cases of this disease were admitted to these hospitals during last week, against 154, 135, and 126 in the three preceding weeks. These hospitals also contained on Saturday last 891 cases of diphtheria, 310 of measles, 127 of whooping-cough, and 69 of enteric fever. The 1538 deaths from all causes in London last week (showing a decline of 75 from the number in the previous week) included 374 which were referred to diseases of the respiratory system, against numbers increasing in the four preceding weeks from 263 to 366. In the 77 towns 159 deaths resulted from different forms of violence, against 180 and 169 in the two previous weeks; and 427 inquest cases were registered. The causes of 41, or 0·8 per cent., of the deaths registered during the week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London and in each of its eight suburban districts, in Manchester, Leeds, Bristol, Bradford, Hull, Nottingham, Leicester, and in 40 smaller towns; the 41 uncertified causes of death in the 77 towns last week included 6 in Liverpool, 4 in Stoke-on-Trent, and 3 each in Sheffield, Birmingham, and St. Helens.

## HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 889 births and 576 deaths were registered during the week ending Jan. 28th. The annual rate of mortality in these towns, which had been equal to 16·6 and 14·8 per 1000 in the two preceding weeks, rose again to 15·7 in the week under notice. During the first four weeks of the current quarter the death-rate in these towns averaged 15·4 per 1000, and was 0·2 below the mean rate during the same period in the 77 English towns. The annual death-rates during last week in the eight Scotch towns ranged from 11·1 and 11·3 in Perth and Aberdeen, to 18·4 in Leith and 19·0 in Greenock. The 576 deaths from all causes in the eight towns last week showed an increase of 32 on the number returned in the previous week, and included 46 which were referred to the principal epidemic diseases, against 56, 51, and 43 in the three preceding weeks; these 46 deaths were equal to an annual rate of 1·3 per 1000, the highest epidemic rates being 3·3 in Paisley and 4·8 in Leith. Of these 46 deaths from the principal epidemic diseases, 14 resulted from whooping-cough, 14 from diarrhœa, 8 from diphtheria, 6 from scarlet fever, 3 from enteric fever, and 1 from measles, but not one from small-pox. The fatal cases of whooping-cough, which had been 18 and 20 in the two previous weeks, declined to 14 last week, of which 5 occurred in Glasgow, 3 in Dundee and in Leith, and 2 in Paisley. The 14 deaths attributed to diarrhœa (of which 10 were of infants under two years of age) exceeded by one the number in each of the two previous weeks. The deaths from diphtheria, which had been 14, 9, and 6 in the three preceding weeks, rose again to 8 last week, including 2 each in Glasgow, Paisley, and Leith. The 6 fatal cases of scarlet fever exceeded the number in the previous week by 4, and included 4 in Glasgow. Of the 3 deaths referred to enteric fever, 2 were returned in Glasgow and 1 in Paisley. The fatal case of measles occurred in Edinburgh. The deaths in the eight towns referred to diseases of the respiratory system, which had been 98, 130, and 121 in the three preceding weeks, further declined last week to 117, and were 6 below the number returned in the corresponding week of last year. The deaths resulting from different forms of violence in the eight towns, which had been 26 and 15 in the two previous weeks, increased again to 20 last week; and 190, or 33 per cent., of the deaths occurred in public institutions. The causes of 21, or 3·6 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 largest English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

## HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,163,596, 597 births and 476 deaths were registered during the week ending Jan. 28th. The annual rate of mortality in these towns, which had been equal to 19·9 and 19·3 per 1000 in the two preceding weeks, rose to 21·3 in the week under notice. During the first four weeks of the current quarter the annual death-rate in the city averaged 20·0 per 1000, whereas in the 77 largest English towns during the same period the death-rate did not exceed 15·6, and in the eight principal Scotch towns the rate was 15·4 per 1000. The annual death-rate last week was equal to 27·5 in Dublin, 15·4 in Belfast, 25·3 in Cork, 22·6 in Londonderry, 20·5 in Limerick, and 11·7 in Waterford; in the 16 smallest of the Irish town districts the annual death-rate last week averaged 20·4 per 1000. The 476 deaths from all causes in the 26 towns last week showed an increase of 46 upon the number returned in the previous week, and included 25 which were referred to the principal epidemic diseases, corresponding with the number in the previous week; these 25 deaths were equal to an annual rate of 1·3 per 1000, corresponding with the rate from the same diseases in the principal Scotch towns. Of these 25 deaths from the principal epidemic diseases, 18 resulted from whooping-cough, 3 from diphtheria, 2 from enteric fever, and 1 each from measles and scarlet fever, but not one from small-pox. The fatal cases of whooping-cough, which had been 8, 9, and 11 in the three preceding weeks, further rose to 18 last week, of which 10 occurred in Dublin, 4 in Cork, 2 in Londonderry, and 1 each in Belfast and in Newtownards. Of the 3 fatal cases of diphtheria, a decline of 4 from the number in the previous week, 2 occurred in Belfast and 1 in Dublin. Both the deaths from enteric fever and the fatal case each of measles and scarlet fever were also

returned in Dublin. The deaths in the 26 towns referred to diseases of the respiratory system, which had been 96 and 105 in the two preceding weeks, further rose to 113 in the week under notice. The 476 deaths from all causes last week included 149, or 31 per cent., which occurred in public institutions. The causes of 23, or 4·9 per cent., of the deaths in the 26 towns last week were not certified either by a registered medical practitioner or by a coroner; the proportion of uncertified causes last week did not exceed 0·8 per cent. in the 77 English towns, and was equal to 3·6 per cent. in the principal Scotch towns.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified: — Deputy Inspector-General G. Welch to the *President*, for special service at Admiralty, reappointed, temporarily, on promotion. Staff-Surgeon: F. R. Mann to the *Terpsichore*, temporarily.

### ROYAL ARMY MEDICAL CORPS.

Colonel T. J. O'Donnell, D.S.O., principal medical officer at Aden, has taken over duty as Principal Medical Officer of the First (Peshawar) Division. Colonel T. P. Woodhouse, Principal Medical Officer of the Scottish Command, has been granted two months' leave of absence with permission to travel in France and Switzerland. The following officers have been appointed Senior Medical Officers of the Coast Defences, as noted against their names: Lieutenant-Colonel R. P. Bond, Eastern; Lieutenant-Colonel G. Wilson, South-Eastern; Lieutenant-Colonel R. R. H. Moore, North Irish; Lieutenant-Colonel T. E. Noding, South-Irish; Lieutenant-Colonel H. M. Adamson, North-Eastern; Lieutenant-Colonel F. S. Heuston, C.M.G., Scottish; Lieutenant-Colonel R. E. R. Morse, Southern; Lieutenant-Colonel R. Kirkpatrick, C.M.G., South-Western; Lieutenant-Colonel A. Dodd, North-Western; and Lieutenant-Colonel P. C. H. Gordon, Western. Lieutenant-Colonel E. J. E. Risk, late administrative medical officer at Belfast, has taken over duties as Commandant and Director of Studies at the Royal Army Medical College, Millbank, in succession to Colonel D. Wardrop, C.V.O. Lieutenant-Colonel H. P. G. Elkington, from Queenstown, has been transferred to the Southern Command. Lieutenant-Colonel J. Maher, from Wynberg, has taken over charge of Queen Alexandra's Military Hospital, Grosvenor-road. Major F. J. W. Porter, D.S.O., from the recruiting staff of the London District, has been transferred to the Southern Command. Major C. R. Elliott, sanitary officer of the Third (Lahore) Division, has been granted eight months combined leave in India from Feb. 1st. Major S. de C. O'Grady has been transferred from Cairo to Khartoum. Major F. Ashe, from Colchester, has taken up duty as Specialist in Midwifery and Diseases of Women and Children to the Ninth (Secunderabad) Division. Major G. E. F. Stammers, from Tidworth, has arrived for a tour of service in India. Major H. J. M. Buist, D.S.O., has joined for duty at Pretoria. Major C. J. Gorman, D.S.O., has been appointed to the temporary command of the station hospital at Peshawar. Captain A. A. Sutcliffe, on arrival home from Straits Settlements, has been posted for duty to Alderney. Captain W. R. P. Goodwin, Captain H. E. J. A. Howley, Captain C. H. Furnivall, and Captain G. F. Rugg have arrived in India. Captain J. W. West, from Dublin, has been appointed Specialist in Advanced Operative Surgery to the Second (Rawalpindi) Division. Captain W. M. B. Sparkes has taken over duty as medical officer in charge of the staff and departments at Beggars Bush Barracks, Dublin, in succession to Major E. G. Browne, who has embarked for India. Major H. L. W. Norrington, from Chatham, has been detailed to embark for Malta in the transport ss. *Soudan* on Feb. 25th. Captain T. W. Browne has been granted six months' leave of absence from India. Captain J. Fairbairn, from Glasgow, has been detailed for a tour of service on the West Coast of Africa (Sierra Leone), embarking about the middle of February. Captain A. Dawson and Captain T. W. O. Sexton have arrived home on leave. Lieutenant J. D. Bowie has taken up duty in the Aldershot Command. Lieutenant H. H. Leeson, from Woolwich, has joined at Cairo.

### INDIAN MEDICAL SERVICE.

Colonel G. W. P. Dennys, on return to India from leave, has been appointed Principal Medical Officer of the Bannu and Derajat Brigades, in succession to Brevet-Colonel J. S. Shearer, C.B., D.S.O., retired. Lieutenant-Colonel A. Buchanan, civil surgeon of Amraoti, has been appointed to officiate as Inspector-General of Civil Hospitals in the Central Provinces, in succession to the late Colonel J. A. Cunningham. Lieutenant-Colonel J. T. Calvert has been appointed to officiate as Principal of the Medical College at Calcutta during the absence on deputation of Lieutenant-Colonel F. J. Drury at Lucknow. Major R. H. Price has been appointed Specialist in Midwifery and Diseases of Women and Children to the Fourth (Quetta) Division. Major F. D. Browne, medical officer of the 112th Infantry, has been appointed to the Medical Charge of the 30th Mountain Battery and the Frontier Garrison Artillery at Kohat. Major W. H. Kendrick, civil surgeon of Nimar, has been placed on special duty under the orders of the Sanitary Commissioner of the Central Provinces. Captain A. W. Overbeck-Wright has been appointed Supernumerary Superintendent of the Agra Central Prison. Captain D. N. Anderson has received an extension of six months' leave of absence from India on medical certificate. Captain G. E. Malcolmson has been appointed to the charge of the Brigade Research Laboratory at Nowshera. Captain C. Shaw has been posted for duty in Burma. The services of Captain R. A. Chambers have been placed at the disposal of the Commander-in-Chief by the Government of India. Captain E. T. Harris has been granted furlough for one year home from India. Captain C. H. Cross has been appointed to officiate as Medical Officer in Charge of the 38th Dogras and to the Medical Charge of the 23rd Mountain Battery. Lieutenant W. D. Keyworth has taken over charge as Specialist in Midwifery and Diseases of Women and Children to the Sixth (Poona) Division, India.

### TERRITORIAL FORCE.

*Army Medical Service.*

Lieutenant-Colonel and Honorary Surgeon-Colonel John Arnallt Jones, from the Sanitary Service, Royal Army Medical Corps (T.), to be Colonel, on appointment as an Administrative Medical Officer of a Territorial Division (dated Jan. 18th, 1911).

*Royal Army Medical Corps.*

*For attachment to Units other than Medical Units.*— Frederick William Price to be Lieutenant (dated Sept. 28th, 1910). Frederick Andrew Worsley Drinkwater to be Lieutenant (dated Dec. 1st, 1910).

### DEATHS IN THE SERVICES.

Brigade Surgeon Lieutenant-Colonel David Renton, A.M.S., of the 15th Hussars (retired), on Jan. 23rd, at his residence in Edinburgh, in his seventy-fourth year. He entered the service in 1864 as assistant surgeon, became surgeon in 1873, surgeon-major in 1876, and retired in 1884. After serving five years in India he took part in the Zulu War in 1879 (medal).

### INDIAN MEDICAL SERVICE EXAMINATION.

The following are the names of the successful candidates, arranged in order of merit, at the recent competition for commissions in the Indian Medical Service, which was held at the Royal Army Medical College and at the Examination Hall, Victoria Embankment, on Jan. 23rd, 24th, 25th, 26th, 27th, and 28th:—

| | Marks. |
|---|---|
| John Scott, M.B., Ch.B.Edin. | 3691 |
| Alister Ralph Speirs Alexander, M.B., B.S.Lond. | 3502 |
| Frederick William Hay, M.B., Ch.B.Edin. | 3362 |
| Indarjit Singh, M.B., B.C.Cantab. | 3357 |
| Sidney Milverton Hepworth, M.B., Ch.B.Leeds | 3284 |
| Harry Slater Cormack, M.B., Ch.B.Edin. | 3240 |
| George Tate, L.M.S.S.A. | 3203 |
| George Selby Brock, M.B., Ch.B.Edin. | |
| Edward Slade Goss, M.R.C.S., L.R.C.P. | 3118 |
| John Frederick Henry Morgan, M.R.C.S., L.R.C.P. | 3111 |
| Krishnan Gopinath Pandalai, M.R.C.S., L.R.C.P., M.B. Madras | 3105 |
| Jyoti Lal Sen, M.B. Calcutta | 3035 |
| Charles Albert Wood, M.B., B.S.Lond., M.R.C.S., L.R.C.P. | 3012 |
| Percival Sandys Connellan, M.R.C.S., L.R.C.P. | 2914 |

### THE OFFICERS TRAINING CORPS.

The Army Council has sanctioned the formation of a second section of a field ambulance to be added to the medical unit of the Dublin University contingent of the Officers Training Corps. It may be mentioned that owing to the rapid

development of the Trinity College contingent the formation of an additional infantry company was recently approved by the War Office. Considerable satisfaction is felt in higher military circles in regard to the progress made by this contingent of the Officers Training Corps.

### THE HEALTH OF THE FRENCH ARMY.

The Paris correspondent of the *Times*, in a letter published in that journal on Jan. 28th, states that the report on the health of the French army for 1909 compares somewhat unfavourably with the corresponding report for the British army. The report shows that since 1902 there has been a steady increase of sickness among the troops, and that the maximum figure was reached in 1908. The effective strength of the French army for 1910 is 27,995 officers and 552,959 men. The proportion of men classed as "constantly sick" tends to increase. The "figures are regarded as a striking argument in favour of calling up for service only the most able-bodied elements among the population."

## GIRLS' SCHOOLS, GAMES, AND NEURASTHENIA.

*To the Editor of* THE LANCET.

SIR,—I want to enlist your sympathy towards an aspect of the prevention of "nerves" which, I am sorry to know, is gaining ground among our best girls. It goes without saying that the greatest of all national questions is the training of the mind and body of the young through instruction and exercise, so that the work in the school may create a general state of "healthy-mindedness" for later life, and thus fit the child in the best manner possible for the domestic, social, and economic conditions of its subsequent career.

We all appreciate the fact that it is the essence of education to promote the development of moral character and to use the facts of human knowledge during school life, so that school experience may not only conduce to an ethical upbuilding, but that the growing mind may also accommodate itself to the intellectual and social requirements of the particular group to which the child belongs. My purpose is not to dispute the views of the schoolman or schoolwoman as to the disciplinary advantage of the humanities and Greek (admittedly for the *élite* of schoolboys only) in school education, or to discuss the value of linguistic teaching for the requirements of modern life and thought. This has already engaged the lay press during the period of head masters' and mistresses' congresses, but as a student of psychology and of morbid mental states I have another and a more serious quarrel with the educationists of to-day, and I think high medical opinion is with me. Mainly my quarrel is with those who have the care and education of our girls, and whilst acknowledging that broadly speaking the materials of instruction for both sexes are of two kinds—viz., those which, owing to their uncertainty and want of exactness (history and literature) demand the exercise of caution and judgment in comparing probabilities, and those others (mathematics and the natural sciences) which deal with what is precise and certain—thus producing a more exact and definite exercise of the reasoning powers; it is not this "knowledge-material" which I call into question, but the method of imparting it to the growing individual by a practically continuous time table at school which now covers every available hour of the day.

The human being is an organism with many-sided facets and capable of reacting to diverse stimuli. Healthy-minded boys and girls are strongly predisposed to react to these stimuli, but there must be a period of rest for reconstruction—katabolism must alternate with anabolism. Young people find a pleasure in exercising their bodily and mental functions, and the joy of activity excites curiosity, which enlarges the mental outlook, adds vividness and gives fulness and colour to the mental content. Such a fundamental response to stimulus necessitates for the pupil a period of repose wherein to reconstruct and analyse the knowledge it possesses. But where is the opportunity in the scheduled hourly time-table of the modern girls' school to reflect upon and to assimilate the knowledge she herself possesses? There should be an opportunity afforded and encouragement given for rest and introspection or to converse about general matters, but the moment class work is over the public and high school girl is driven compulsorily to the playing fields to practise games which do not in themselves sufficiently supply a training for all the muscles of the body, and this undue, indeed *wicked*, devotion to pointless athleticism produces "gregariousness" rather than self-reliance. The violent games, such as hockey and football, cricket, and even golf, especially when carried to such an excess, are responsible for the "insurgency" of the modern girl against domestic responsibilities and the common duties of life; moreover, they tend to make the body a motor machine rather than the expression of a healthy and refined mind.

I know there is a widespread and increasing discontent on the part of thoughtful parents with the modern system of the absolute separation of games and class-work. I maintain, as an alienist having some experience of the failures of the schoolmaster and schoolmistress, that the great drawback of the teaching of to-day is the revival of the mediæval belief in the separability of mind and body, which is responsible for the bifurcation of educational aims and the consequent direction of educational methods towards the physical development of the body on the one hand and towards mental forcing on the other, there being no attempt made to establish a proper coördination of the different branches of "knowledge-material." This practice is due to the failure of academical teachers of pedagogy to contemplate the boy or girl from the proper biological standpoint. The keynote of education, on this conception, from the nursery onwards, is "knowing through doing"; each movement of the body is associated with a mental state, and exercise should be an adjunct to the cultivation of the mind, not an end in itself.

If the present mental lukewarmness of girls towards the principles of housekeeping, the care of infants, the true instincts of motherhood, and civic duties is to be changed, the wild cult of athleticism by girls and the congested and continuous time-table prepared for them without a moment's spare time from bed-rising to bed-retiring must be abandoned or extensively modified. It is a fact that excessive devotion to games is the cause of much of the mental restlessness, the frantic rush towards "What shall we do next?" the discontent and the inaptitude for work in many girls, who, formerly afraid of nothing, now return from school to their homes not as the finished article, but mentally numb and cold from a lack of resourcefulness and self-confidence. Such states of mind and body carve the way for the worst type of "nerves" or neurasthenia, and they create in addition those morphological characters described as the "cricket stoop," the "hockey walk," and the "golf stride," or the "football roll"!

I need only quote the following from the *Times* of Jan. 3rd: "There is probably no game which affords a greater scope than golf for all possible forms of nervousness, not only for sheer terror, but for every conceivable foolish fancy which can impair the properly concentrated frame of mind," and *a fortiori* this is true of the more intense and energetic games. The bodily changes referred to above are caused by an environment of undue athleticism, and they imply a change also in mental characters, so that the gentleness, the æsthetic beauty, and the refinement of our home-life are doomed to disappear unless this "curse" is modified, and I feel that their warning sign that something is wrong comes none too soon!

I am, Sir, yours faithfully,

Claybury, Jan. 23rd, 1911. ROBERT JONES, M.D. Lond.

## NODULAR FIBROMYOSITIS.

*To the Editor of* THE LANCET.

SIR,—I should like to corroborate and accentuate all that has been said regarding this malady in the excellent and helpful article by Dr. Telling in your issue of Jan. 21st. Writing solely from the position of an ordinary practitioner, I can positively assert that it will well repay any one in practice to make a study of this condition and a systematic search for these nodules in all cases of muscular pains. The disease is not sufficiently well recognised. For example, Dr. Telling himself, evidently now an enthusiast and an authority, says

in his contribution that "some years ago he was sceptical of the existence of these nodules."

In my own case, although some years in practice, I was unaware of the real nature of this complaint, and certainly of its extent, until it was pointed out to me by Dr. John Macintyre, the well-known throat specialist. Since I have been indebted to him for an understanding of the disease and its recognition, I have been able to clear up with remarkable ease many obstinate cases of lumbago, myalgia, and muscular pains generally.

One can hardly hope to add anything of value to the striking cases illustrating Dr. Telling's paper, but a hint of what one finds in everyday work may be useful to anyone looking into this condition for the first time.

One of my first cases was a perfectly helpless policeman who had to be carried from one room to another, the action of the muscles in the gluteal region being quite lost. He had taken, *ad nauseam*, aspirin, pot. iodid., and alkalies, had suffered blisters, leeches, and turpentine fomentations without any benefit, and was supposed to be suffering from chronic double sciatica. When laid on his abdomen on a couch, the arms dependent, and the erector spinæ well-oiled, these muscles were studded with numerous nodules. All around the origin of the gluteus maximus, at the crest of the ilium and extending down to the sacrum nodules were easily felt and were exceedingly painful. Owing to the patient wasting, the integument was loose and freely moveable over the muscle, and the nodules gave the sensation to the hand of running over peas. This case made an excellent recovery at the hands of a football-trainer, to whom the nature of the complaint and directions for using the thumbs were explained, which shows that those unable to obtain trained massage may do well without. Possibly, however, if not in expert hands they are not really cured, but the relief from pain and the returning power are remarkable. In coachmen and vanmen I have found nodules, and they have invariably been the origin of some severe and commanding pain, and I have never failed to find the pain disappearing permanently after treating these nodules by massage with the thumbs.

In conclusion, it is distinctly noticeable that these sufferers from nodular fibromyositis are generally people who have not had an actual rheumatic illness; they are often highly strung people and generally fairly active. Such articles as Dr. Telling's make a welcome appearance in the pages of THE LANCET because the subject is of genuine interest and much help to the general practitioner.

I am, Sir, yours faithfully,
HARRY M. ROBERTS, L.R.C.P. & S. Edin.,
L.R.F.P.S. GLASG.

Stevenston, Ayrshire, Jan. 27th, 1911.

*To the Editor of* THE LANCET.

SIR,—In his very instructive paper on "Nodular" Fibromyositis, an Everyday Affection, and its Identity with so-called Chronic Muscular Rheumatism, in your issue of Jan. 21st, Dr. Maxwell Telling has done good service in drawing attention to a clinical entity which, as he rightly points out, has received too little attention in English medical literature. He is, however, hardly correct in assuming that no adequate description of this condition exists apart from what is contained in the admirable paper published by Dr. Stockman in 1904. If Dr. Telling will refer to the article on Chronic Rheumatism in the "Encyclopædia Medica," Vol. X., 1902, he will find there a very full presentation of the subject along lines which are in all essential respects identical with those set forth by him in his very instructive paper.

I am, Sir, yours faithfully,
Edinburgh, Jan. 22nd, 1911. CHALMERS WATSON.

## THE ANTISEPTIC OR ASEPTIC METHODS.

*To the Editor of* THE LANCET.

SIR,—I read with interest the papers which appeared in THE LANCET of Nov. 27th, 1909, and Jan. 1st, 1910, and the correspondence which followed on the results obtained by the antiseptic or aseptic methods of wound treatment. The percentage of sepsis after operation in clean cases by either method as quoted in these papers did not appear to be as good as might have been expected, and I thought that they would not compare very favourably with the results which are obtained in the Dublin hospitals. However, as I had no statistics ready to hand I was unable to be certain on this point. In order to be able to make some comparison I have had very careful records kept at the Royal City of Dublin Hospital of all the clean cases operated on by me during the last 12 months. Dividing the cases into classes, as in the St. George's Hospital statistics, the numbers come out as follows:—

| — | Cases. | Infected. | Percentage of infection. |
|---|---|---|---|
| Radical cure of hernia ... ... ... ... | 8 | 1 | 12·5 |
| Excision of breast ... ... ... ... ... | 9 | 0 | *Nil.* |
| Operations on the thyroid ... ... ... | 3 | 0 | ,, |
| Operations on the male genital organs | 7 | 0 | ,, |
| Operations for appendicitis ... ... ... | 11 | 0 | ,, |
| Miscellaneous ... ... ... ... ... ... | 65 | 1 | 1·5 |
| Totals ... ... ... ... ... ... ... | 103 | 2 | 2 |

The miscellaneous cases include operations on bones, excision of joints, laparotomies, operations on tuberculous and malignant glands, spina bifida, brachial anastomosis, amputations, excision of varicose veins, &c. In both the cases that became septic the anæsthetic was badly taken, and it was impossible to prevent the risk of soiling the wound. In the first, a boy operated on for inguinal hernia, chloroform was the anæsthetic used, and the patient stopped breathing and artificial respiration had to be performed for several minutes; though this caused a complete disturbance of the operative field there was only a slight skin infection, and the patient was discharged from the hospital healed in three weeks. In the second case the patient, a man, had a large hæmatoma and ossifying myositis in the upper part of the thigh; he took the ether very badly, and was constantly struggling during the operation, which was a long one, and though the towels surrounding the field of operation were frequently disturbed there was only a superficial infection of one end of the wound, which healed within a fortnight. So although at first sight the percentage of sepsis (about 2 per cent.) seems high, it might be considered that it would have been justifiable to omit these two cases, when the percentage of sepsis would have been *nil*. This is, of course, a very small number of cases from which to draw any conclusions, but they form a consecutive series of operations performed during one year by one surgeon under the ordinary conditions of a general clinical hospital with frequently changing residents.

These operations were performed by the aseptic method, no chemicals being used except in the disinfection of the patient's skin and the hands of the operator and assistants. All those partaking in the operation wore caps but not masks, the sister and assistants wore gloves; but as a rule I do not wear gloves myself, being satisfied with the results of the use of Harrington's solution for the sterilisation of my hands, as described by me in the *Practitioner* for February, 1906. Finally, the test of whether the case healed aseptically or not was the absence or presence of a single drop of pus.

I am, Sir, yours faithfully,
Dublin, Jan. 14th, 1911. R. ATKINSON STONEY.

## THE EXPERIENCES OF DEAFNESS.

*To the Editor of* THE LANCET.

SIR,—The enclosed letter, from a patient whose operation has already been published by me in THE LANCET, is so interesting that I think it may be appreciated by your readers, especially when considered in conjunction with the care of the ear in children. It is addressed to yourselves.

I am, Sir, yours faithfully,
Jan. 24th, 1911. MACLEOD YEARSLEY, F.R.C.S. Eng.

[ENCLOSURE.]

*To the Editor of* THE LANCET.

SIR,—It has been suggested to me by more than one medical man that I should record the experience of being completely deaf. In my case the loss of hearing was gradual, accompanied for a long time by most severe attacks of vertigo, amounting at last to fits, and cured only by an aural operation. [Cf. THE LANCET, Sept. 19th, 1908, June 19th, 1909.]

I have now been quite deaf for about two years. What is the sensation? There is a sense of blankness. I feel always in a condition of expecting to hear, yet never realising the expectation. I cannot describe it in any other way. I have often observed that deaf people have a surprised look about them, as though they were wondering why they cannot hear, and sometimes I wonder if I am getting the same look, for it is not becoming. Then, together with this sense of blankness is the ever-present sense of loss. This at times is overwhelming. I cannot now remain in a room where music is being performed, as the fact that I cannot hear it and never shall is too much for me. For the same reason my duties as a clergyman have become a real and heavy burden, and most of the joy I once had in them has gone. This doubtless is the cause of the depression common to most deaf people, whereas the blind who possess the faculty of hearing are usually cheerful.

But the loss of hearing is undoubtedly felt more from its social side. Neither lip reading nor sign language can compensate for the loss of the human voice. We cannot join freely in the conversation of the family circle; and the funny story ceases to be really humorous when interpreted by signs. Rightly or wrongly, this encourages the tendency to withdraw from society and social life. You cannot hear, it is most difficult to join in the conversation, it seems only waste of time to remain, and the time one feels would be better spent in reading or writing.

One of the most distressing results of this total deafness is, to me at least, the horror of the awful silence in the dark, and I should like to know how far this is the experience of others similarly situated. Some time ago I was frequently out alone in my rural parish on very dark nights, but the scares I endured by blundering against people I could not hear approaching or whom I overtook completely unnerved me. But now it is torture to lie awake alone in the dark—not so much from any actual fear as from the sense of helplessness and insecurity; one feels in consequence the risk of being surprised by, perhaps, a cat jumping on the bed, or someone coming into the room without a light, and so forth.

In connexion with this is now the inability to walk in the dark at all. I cannot venture even to walk across a room in the dark as there always seems a tendency to fall forward, which has in fact actually happened on several occasions. The last time I attempted to walk in the garden at night I fell down, and on getting up fell down again, and only got indoors by feeling my way along the wall like a blind man.

I find I am by degrees losing the memory of certain sounds, which since memory cannot now be assisted by external aid it is impossible to recover. Certain musical airs, &c., once well known but now forgotten, I cannot possibly recall, while new sounds and new voices I cannot even realise—e.g., I can realise my wife's voice but not the voices of my children, whose adult voices I have never heard. Also, strange to say, I cannot now even imagine the sounds of some musical instruments, notably the church organ, and also certain outdoor sounds, bird notes, &c., I have completely forgotten. Being quite unable to hear my own voice, I have lost all control over it, and am told it has greatly altered since my deafness increased, running up sometimes into a falsetto and sometimes being scarcely audible. In church it is most puzzling to know if I am anywhere within the right pitch. I still enjoy the theatre, and find it most fascinating to watch the developments of the play through the acting alone, while a ballet appears much more intelligible without the music. On the other hand, the effect of seeing people sing and hearing no voices is irresistibly comic. People singing in church often look as if they are suffering untold agonies.

If there are any compensations I have not yet found them, except perhaps that one can read and write undisturbed in a noisy room, and that one's meditations are not disturbed in the London streets or the interior of a motor-bus.

Yours faithfully,

All Hallows' Vicarage, nr. Rochester. F. J. HAMMOND.

## THE MEDICAL LANGUAGE OF THE THIRD GOSPEL.

*To the Editor of* THE LANCET.

SIR,—I read with much interest the annotation under the above heading in your issue of Jan. 7th. I should like to direct attention to an interpretation of the word σκωληκόβρωτος (translated in both versions of the Bible "eaten of worms"), which agrees with common experience of tropical pathology, and so supports very forcibly, I venture to think, the view that the author of the Acts of the Apostles was a good physician who employed an exact and appropriate term in describing the fatal malady of Herod Agrippa the First.

Kirby and Spence, in their "Introduction to Entomology,"[1] discuss the phrase in question and point out that the word scolex (σκώληξ) was used to denote the larva of an insect. So Aristotle[2] employs it when he says that all insects produce a scolex or are larviparous. And when Galen prescribed a remedy for ulcers infested with maggots he used the same word. Liddell and Scott's "Greek Lexicon" (edition 1883) refers to Theophrastus, who writes σκωληκόβρωτος of a worm-eaten tree—i.e., a tree worm-holed by grubs.

It is a matter of everyday practice in the East to find the larvæ of flies inhabiting wounds and ulcers, a condition known as myiasis.[3] It is more than probable that the malady of Herod Agrippa was complicated by this condition, the concomitant sepsis aiding, if it did not cause, the fatal issue. Two well-authenticated cases may be quoted in corroboration.

The first is that of the Emperor Galerius, of whom we read in "The Decline and Fall of the Roman Empire"[4]: "His body, swelled by an intemperate course of life to an unwieldy corpulence, was covered with ulcers, and devoured by innumerable swarms of those insects who have given their name to a most loathsome disease." In a footnote Gibbon says, "Lactantius and Eusebius describe the symptoms and progress of his disorder with singular accuracy and apparent pleasure," but it seems from the passage cited above that the historian took the condition to be one of phtheiriasis.

The second case referred to by your contributor is that of Antiochus Epiphanes, the graphic description of whose death is to be found in the Apocrypha.[5] Here we have a chariot accident—severe injuries to the limbs—septic infection of the wounds, perhaps communicating with fractured bones, invasion of the fly-blown ulcerated surfaces by maggots, and subsequent death from septic absorption:—

> It came to pass that he fell down from his chariot, .....; so that having a sore fall, all the members of his body were much pained.
>
> * * * * * *
>
> So that the worms (σκωληκες) rose up out of the body ....., and whiles he lived in sorrow and pain, his flesh fell away, and the filthiness of his smell was noisome to all his army.
>
> And the man, that thought a little afore he could reach to the stars of heaven, no man could endure to carry for his intolerable stink.
>
> * * * * * *
>
> So died he a miserable death in a strange country in the mountains.

In view of these parallel cases and ancient instances, I cannot but accept the rendering set forth by Kirby and Spence in their "Entomology," and at the same time give all credit to the medical accuracy of the author of the Acts of the Apostles.—I am, Sir, yours faithfully,

Birkdale, Lancs., Jan. 17th, 1911. D. M. HUTTON.

## THE ADMINISTRATION OF STIMULANT DURING ANÆSTHESIA.

*To the Editor of* THE LANCET.

SIR,—I desire to bring to your notice a method of producing anæsthesia which I have not hitherto seen described. The anæsthetic consists of a mixture of ether, alcohol, and oxygen. The apparatus, which is extremely simple and inexpensive, is composed of: 1. An ordinary Schimmelbusch mask, or, better still, although not essential, Hewitt's modification, which is specially adapted for the exhibition of oxygen with anæsthetics. 2. A glass bottle with a rubber stopper, through which are led two pieces of glass tubing, the longer of which reaches to within one inch of the bottom, and the shorter extending for one to two inches beyond the under surface of the rubber stopper. 3. A cylinder of oxygen. 4. A supply of rubber tubing.

The glass bottle is filled to the depth of two inches with absolute alcohol. Rubber tubes are fitted on to the two glass tubes, the one attached to the longer being fixed at its other end to the nozzle of the cylinder, and the other from the shorter of the tubes leading to the inhaler. Oxygen is then bubbled through the alcohol and the administration of ether commenced. The apparatus can be equally well used in the administration of other anæsthetics.

I have found this method very useful in bad cases where the patient prior to the operation is in a condition of shock, and also in those conditions where one anticipates and wishes to obviate shock from the operation itself. It has proved very successful in laparotomy for intussusception, ectopic gestation, &c.

I am, Sir, yours faithfully,

H. M. ANDERSON,
Resident Surgical Officer, Royal Infirmary.

Preston, Jan. 23rd, 1911.

## CATGUT STERILISED BY IODINE.

*To the Editor of* THE LANCET.

SIR,—I should be glad to know the experience of surgeons who use catgut sterilised by the iodine method for the deep sutures in their cases. In a long series of cases here where this suture has been used about 50 per cent. show the formation of a variable quantity of orange-coloured serum in the deeper parts of the wound. This serum collects, as a

[1] Seventh edition, p. 51.
[2] DeGenerat. Animal., l. 1, c. 2.
[3] Encycl. Medica, vol. viii., p. 211.
[4] Gibbon, Edition 1802, vol. ii., p. 213.
[5] II. Maccab. ix.

rule, within the first week after operation. There seems to be but a slight tendency in these cases for absorption of the serum to take place, and in hardly any case does suppuration follow its collection. In some cases there is a variable rise of temperature, seldom exceeding a degree and a half, to indicate that healing is not proceeding satisfactorily, but in many there is no evidence apart from inspection to show that this is the case.

On releasing the fluid by passing a probe between the skin sutures, or by removing a stitch, the parts fall together and healing rapidly follows. The formation of fluid in the wound naturally delays consolidation of the scar, and I should be glad to learn any means whereby this accident could be avoided. The catgut is sterilised as follows: the raw gut is first dipped in a 70 per cent. alcoholic solution of biniodide of mercury (1-1000) and is then kept in tr. iodi for at least ten days before use.—I am, Sir, yours faithfully,

R. S. CAREY, M.R.C.S. Eng., L.R.C.P. Lond.,
House Surgeon, The Infirmary, Peterborough.

Jan. 25th, 1911.

## THE INSPECTION AND TREATMENT OF SCHOOL CHILDREN.

*To the Editor of* THE LANCET.

SIR,—As a member of the committee of management of the Central London Throat and Ear Hospital, and as chairman at several meetings during which the question of the medical treatment of school children under the care of the London County Council was discussed, I beg leave to state that my colleagues were unanimously of opinion that at the present moment it was not advisable to enter into any commercial undertaking or any kind of agreement whatever by which the London County Council would have a right to claim medical service at our hospital.

What we did was to pass a resolution to the effect that we were "willing as hitherto to receive these children from the London County Council schools who are suitable for hospital treatment so far as the capacity and resources of the hospital will allow." This resolution has not been departed from, but I understand that it has been misinterpreted by many medical practitioners with whom the hospital has such intimate and cordial relationship.

During the last year we have treated in the out-patient department 346 children whose parents had been directly recommended to seek medical relief for affections of the throat, nose or ear from the various education committees in connexion with the London and the neighbouring county councils. As members of the community every one of these children was a suitable hospital patient, and they were admitted as members of the community, and not by virtue of their relationship with the county councils. Many of these children were sent by medical practitioners who use this hospital to such a large extent, no less than 35 per cent. of the out-patients and 57 per cent. of the in-patients coming direct from their own doctors.

This mode of action on our part appeared to be the best adapted to satisfy the general medical practitioners whose legitimate interests we strive to safeguard, and it approached as nearly as possible the ideal of making this hospital a consultation centre between the practitioner, his patient, and the specialist.—I am, Sir, yours faithfully,

CARMICHAEL THOMAS.

Inverness-terrace, Hyde Park, W., Jan. 31st, 1911.

## THE NOMENCLATURE OF THE SUPRARENAL PRINCIPLE.

*To the Editor of* THE LANCET.

SIR,—I must apologise for intruding in this controversy, and would not have done so had Mr. Braithwaite not introduced my name. I am sure there is no intention on the part of Mr. Braithwaite to foster a principle which is not only quite unjust to manufacturers but also misleading to pharmacists, and may, indeed, be generally mischievous in its effect; yet logically this is the untenable position to which he is driven by arrogating to himself the power to substitute a synonym in the place of the name adopted by the author; in other words, to "adjust" a clinical report in such a manner as would not, it is safe to say, receive the sanction of the author. He must start with the general hypothesis that all the preparations of the suprarenal gland now on the market are identical, and if used under identical conditions will produce identical results—a hypothesis which is falsified by analyses and clinical reports, and, moreover, is not claimed by the respective manufacturers. This being so, and the pharmacist being unable to identify the individual product, of what *practical* value are Mr. Braithwaite's abstracts? It is quite obvious that they will be misleading; and if, as is quite possible with a sensitive drug of this nature, the desired therapeutic effect is not produced, dissatisfaction ensues, and the author, the prescriber, the pharmacist, and the drug itself are, in that particular connexion, discredited.

The quotation of mine to which Mr. Braithwaite refers has, it seems to me, little bearing on the subject, except to make it more difficult for him to justify the substitution of the synonym. Further, it makes this portion of the letter inconsistent with his action and with the final paragraph of his letter, where he tacitly admits that the name used by the author indicated that a particular preparation had given a definite therapeutic effect.

In conclusion, I can only express the hope that, in justice to all, Mr. Braithwaite will either give honour where honour is due, or if this course is not permitted him by the ethics of the "Year Book of Pharmacy," that he will abstain from a system of substitution as improper as it is misleading.

I am, Sir, yours faithfully,

London, Jan. 31st, 1911. THOMAS MABEN.

## MORE GRATUITOUS SERVICES.

*To the Editor of* THE LANCET.

SIR,—The following correspondence may interest your readers, as it refers to a subject in which we are all interested. I should like your opinion on the matter, which, briefly, is as follows.

A servant (injured at work) brought me a message from her master that the insurance company required a medical certificate. I replied that if he would apply to me direct and pay the fee for it he should have it. I enclose a copy of his reply and my answer.—I am, Sir, yours faithfully,

Jan. 30th, 1911. BETA.

[ENCLOSURE.]

DEAR SIR,—I am insured against any claim under the Workmen's Compensation Act, and the matter is now between Mrs. —— and the Insurance Company. They ask for a certificate which *she* must get, as the matter is entirely out of my hands. Yours truly,

—— ——.

DEAR SIR,—As an act of courtesy I enclose you the certificate you require, but I must enter a protest against the manner in which the gratuitous services of the medical profession are so frequently claimed—apparently as a matter of right—for the pecuniary benefit of others. As you appear entirely to misunderstand the position, may I briefly explain it?

A is an employer of labour (in this case yourself); B is a servant (in this case Mrs. ——); C is an insurance office. Under the Workmen's Compensation Act B has a claim against A for wages. To limit his liabilities or recoup his losses A insures with C, the latter undertaking to carry through the negotiations with B, and pay A's liabilities.

Nevertheless, C is only acting on behalf of A, and should C be unable to meet its liabilities, or through some technical loop-hole be enabled to plead non-liability, B's claim against A would still exist; whilst C's refusal to pay would concern A only and not B, the latter having no legal interest in the private contract between A and C.

It is to enable A to transfer his liabilities to C that the certificate is required. If this be refused A will be the loser, for C will not pay without proof, whilst under the Act A must still pay B, and obtain what redress he can from C for breach of contract.

Thus the certificate is required entirely for the benefit of A, and its non-production will not in any way affect B's position, whose legal claim against A is still intact.

Therefore A is undoubtedly liable for the expense of obtaining the necessary certificate. Yours truly,

—— ——

*** Beta has put his case quite correctly in his letter to A, the employer, but how far he may have affected his right to claim a fee from A by writing that he sent a certificate "as an act of courtesy" we do not prophesy. He would have been wiser if he had refused the certificate until he obtained either payment or promise of payment from A, who, of course, is liable to compensate his own servant but has indemnified himself by insuring against that liability. In order to obtain the benefit of that indemnity A needed a certificate to send to his insurance company; he asked for it, and it is for him to pay for it. So far from the matter being entirely out of his hands, neither he nor his servant can alter the obligations imposed by the Workmen's Compensation Act.—ED. L.

(*Continued from p. 267.*)

### *The Poorest Houses and the Poorest Tenants.*

THE houses in Merthyr that are defective and, in fact, unfit for human habitation are nearly all old houses, and in many cases the expiration of the leases is so near at hand that the owner naturally objects to incur any outlay for repairs. The authorities, it may be said, should proceed all the same, and this they have done in many instances, but not in all. The fact is that the rents, especially for the old houses owned by the Dowlais works, are very low. One cottage I visited had two small bedrooms upstairs and one downstairs, so that there were three beds in all, and the rent was only 10*s.* a month. There are a considerable number of old cottages let at 9*s.* 6*d.* per month. A new cottage could not be obtained for twice as much; 20*s.* a month is considered a low figure. When a family, or perhaps an old couple, are reduced to the lowest straits of poverty it often happens that their most valuable asset is the fact that they are in occupation of an insanitary dwelling for about half the rent they would have to pay elsewhere. If the law were enforced they could be turned out. But their house may be insanitary only because it is somewhat dilapidated, and more especially because it is overcrowded. The drains are in order and do not pass under the dwelling, which is well exposed to plenty of light and fresh mountain air. To turn these people out when there is no better place for them to live in would be mere cruelty. If they are a dirty, degraded lot, to place them in a better house where they must pay twice as much rent would only add to their poverty and consequent degradation. The evidence, especially at Merthyr, goes to show that good property quickly deteriorates under such tenants, unless the change of dwelling coincides with a favourable change of occupation. Something is needed to reawaken hope and ambition, atrophied by long periods of misery and semi-starvation. The ideal would be to obtain more remunerative employment at the psychological moment of the enforced removal from a slum to a decent dwelling. Then the better house and the better pay coming hand in hand would engender the confidence and the courage necessary to make these poor and crushed sections of the community enter the lists once more and take an active part in the struggle for life. A real regeneration might be thus brought about, otherwise the friendly counsel of sanitary inspectors, of nurses, and of other reform agencies falls on the ears of apathetic people who have not the vitality to avail themselves of the advice given. People only improve, take more pride in their homes, and attempt to keep them clean when they remove voluntarily because they had succeeded in getting more advantageous employment. This is so well known that when the borough council was compelled itself to build houses those who were opposed to such municipal intervention urged that the most degraded of slum-dwellers should be admitted into the council houses. This was a certain way of ensuring the financial failure of the enterprise and thus limiting its scope. The council, however, was not satisfied to accept only the "ne'er do weels" for tenants, though there is an amusing story told how four council houses were let to very disreputable and undesirable tenants. On each occasion the house had been taken by a very decent-looking person wearing something like a sealskin jacket. An inquiry, however, revealed the fact that, though the tenants differed, the same smart imitation sealskin jacket had, on each occasion, been borrowed just to produce a favourable impression during the negotiations.

### *Dwellings Built by the Corporation.*

The council of the borough of Merthyr, acting under Part III. of the Housing of the Working Classes Act, has built 100 houses in the Penydarren district which are let at 21*s.* per month; in Penywern, 38 houses let at 17*s.* a month; in Twynyrodyn, 35 houses let at 18*s.*, and 15 at 22*s.* a month; at Dan-y-Deri, 38 at 22*s.*; and in Penywern there are 68 more houses that are not yet quite completed. This makes a total of 294 houses built and rented direct to the tenants by the corporation. Let at the rents mentioned, these houses pay and do not add any burden on the rates. There are always more applicants than there are houses to let, and it is now proposed that the council should build houses in the Plymouth and Park Wards. In the same districts just mentioned 304 houses were built by private enterprise. Nevertheless, this is obviously insufficient. Of the two-roomed houses inspected in 1907 the proportion of overcrowding was equal to 29 per cent. This increased to 38 per cent. in 1908 and to 42 per cent. in 1909. The increase of overcrowding in three-roomed houses was from 12 per cent. to 19 and, finally, to 26 per cent. during the same three years. Overcrowding is here defined as meaning that the inmates exceeded double the number of rooms. The overcrowding is mainly in the two- and three-roomed houses. The four-roomed house seems to be the most suitable type, but the five- and six-roomed houses are, again, more apt to be overcrowded, as it generally means the taking in of numerous lodgers.

The 38 houses the council built at Penywern, Dowlais, were all four-roomed dwellings, two rooms downstairs and two upstairs, and a bath which is supplied with hot water from a boiler heated by the kitchen range. The cost for each house was £134 10*s.*, and, as the repayment of the loan is extended over a period of 60 years, they can be let for 17*s.* a month. It should be stated that there is also the cost of constructing the road for these houses, and this raised the outlay to £150 per house. At Dan-y-Deri, Merthyr Vale, the council had acquired some land, and conceived a more ambitious plan of building 38 houses that were to cost £242 each. But the Local Government Board objected that this would mean too high a rent for the class of tenant it was desirable should be housed. So the scheme was therefore altered to reduce the cost to £200. At this lower price the houses contain a kitchen which, as usual in such cottages, is the general sitting-, dining-, and living-room, and also a scullery. On the first floor there are three bedrooms, the largest having a cubic capacity of 1080 feet. These houses let for 22*s.* a month. The first lot of corporation houses were erected in 1903 by the urban district council before Merthyr was promoted in November, 1905, to the rank of a county borough. They form two streets appropriately called Urban-street and Council-street. These are situated just above, and a very short distance beyond, the terrible slum on the hillside that overlooks the Dowlais Ironworks. They afforded a pleasant contrast after visiting the squalor and misery that were so close at hand. The roads are broad, and an extensive space is left behind for gardens and fresh air. The houses with their dressed stone fronts look very prim. The inhabitants take pride in keeping everything bright and in good order. The interiors I visited were very clean, and the only fault I can find is that no baths are provided. Here the land costs 1½*d.* per square yard on a lease of 999 years, the back lanes being thrown in free. As matters now stand, the borough owns a good deal of land on similar leases, and it has become practically a freehold, for there is no one remaining to claim the ground-rent. The council experiences no greater difficulty in obtaining land than private builders; and, indeed, for the first housing schemes brought forward eight or nine years ago they obtained land below its market value. It was the late Mr. Thomas Williams, an iron-master, who offered land on these exceptional terms, for he was very anxious to help in the rehousing of the poorer sections of the population. A fair amount of public spirit, I was assured, has been displayed by the ground-landlords of the neighbourhood.

### *Dwellings Built by Private Enterprise.*

From these council houses I went to several new streets recently erected by private enterprise. Among these, one of the most interesting was Baden-street, because several of the inhabitants who have been driven out of the worst slums have gone to live there. The street is admirably situated on a hillside with large garden space behind and open fields close at hand; in fact, the inhabitants may be considered as living in the country, though they are not far from the centre of the town. Some of the houses are quite nice, while others already wear an appearance of dilapidation. The paper of the partition walls has been torn off, exposing the laths and plaster. The separation wooden rails in the back gardens or yards have been torn up and probably burnt for firewood. Indeed, the stair banisters are also at times burnt.

People who are starving suffer greatly from the cold, and they cannot afford to buy fuel. Other houses had windows broken. The tenants could not have fresh panes put in. Their poverty might be reduced if they grew vegetables in the large garden space behind the houses, but they are too listless. Also, many are but temporary tenants. This is one of the great difficulties. People from all parts are attracted here in the hope of getting some work. They have no intention of settling down and take no interest in their home. On the other hand, the houses of the native Welsh are easy to recognise, first, because they are much better kept and, secondly, because there is always an attempt made to grow flowers at the window. Inside there are surely some brass candlesticks or other brass utensils and ornaments that are kept in the highest state of polish and prove by their glitter some pride in domestic environment. But in Baden-street there were houses containing no furniture worthy of the name, and certainly nothing whatsoever that was ornamental. Many of the inhabitants were dressed in rags and the children were barefoot, which was perhaps preferable to wearing the remnants of shoes such as the parents carried fastened to their feet. The street was clean, for the inhabitants are prosecuted if they throw out refuse or empty dirty water in the gutter instead of pouring it out over the gully. But they take their revenge by throwing out tins and gallipots, soiled bedding, and sordid, filthy rags into the back gardens, which were intended to provide vegetables and flowers for happy prosperous homes.

*The House Famine.*

Not far from here there are in Queen's-road some cottages built by the council that have a beautiful outlook over the hillside. There is a small room by the side of the large living-room in the front, while there are a scullery and bathroom at the back. Above are two or three bedrooms. The tenants seemed quite proud of their homes and did not degrade the property. The rent was 22*s.* a month, and these houses are close to the park which has been made in an old quarry so hollowed out that it looks like an amphitheatre. Here the municipal band plays in the summer, and this is much appreciated by the Welsh, many of whom are born musicians. On the other hand, while these improvements have been effected, the riverside and China districts, which some 12 years ago were sinks of immorality and vileness, are now completely swept away. Still, and in spite of all these endeavours, the housing problem remains unsolved and the official statistics quoted above show that the overcrowding is increasing. The borough council boasts that it stands in the first rank among the boroughs of the kingdom for activity in the work of housing. The population of Merthyr is estimated at somewhat less than 79,000, and the council has built close upon 300 houses. There are not many towns that have done so much in proportion to their populations. On the other hand, public meetings have been held at Merthyr and resolutions carried calling upon the borough council to erect, not 300, but 2000 houses. Certainly the latter figure is nearer the mark if the necessities of the situation are to be satisfactorily met; but even then a plentiful supply of houses does not meet all the difficulties. We have seen that 17*s.* a month is the lowest possible rent for a good house that cost in all £150 to build. On the other hand, the poorest sections of the population still find houses which they rent at less than 10*s.* a month. Therefore, of two things one must occur—either the wages these people earn must be increased or cheaper houses must be built. If there is to be no increase of wages the house must not cost more than £90 to £100. Even then it is a poor business for those who find the capital. Ten shillings a month on £100 only represents 6 per cent., and we should count 2 per cent. for repairs and something more for the sinking fund, to say nothing of rates and taxes. Obviously wages should be such as to admit of the payment of more than 10*s.* a month for rent. It was not easy to ascertain what the unskilled labourers earn. Some persons assured me that in the ironworks they only obtained 1*s.* 11*d.* "a turn," while others insisted that at Dowlais they received 2*s.* 11*d.*; but everyone agreed that the work was very irregular. What is called "a turn" practically amounts to a day's work, and it is only when the works are very busy that these men can hope to earn from 16*s.* to 18*s.* a week. These men and the miners' assistants cannot afford the rent of a new and decent cottage. In the building trade unskilled labour is paid 5½*d.* per hour, and a wages book was shown me which proved that 52 workmen had earned £40 18*s.* the previous week (considerably less, therefore, than £1 a week). A large number of poorly paid workers, including some of the lower type of Irish, have drifted here. They work, but often only in such a fashion that it is doubtful whether it is worth employing them. Many are social wrecks and have not the manhood remaining to make a genuine effort. These are the sort of people who create insanitary conditions and keep the sanitary inspectors constantly at work. Thus last year legal proceedings were taken in respect to 160 houses. Of these, 87 were altered and rendered habitable, 26 were closed, and in 48 cases the closing orders had to be postponed because it was impossible to find accommodation for the tenants elsewhere, and here we come back to the bedrock difficulty that there are not sufficient houses available. In addition to the above cases that came under the Housing of the Working Classes Act, the sanitary inspectors served 263 legal notices under the Public Health Act, which resulted in a considerable amount of structural alterations and repairs. Thus, while overcrowding and misery still prevail, the surroundings are constantly watched and kept as wholesome as the circumstances permit.

*The Cry for More Houses.*

Many of the worst dwellings, and these are generally very old cottages, are saved by their situation on a hill-side. Here, I would again insist, they are exposed to the wind and bathed in light. Nothing overtops them, nothing puts them in the shade. The inhabitants may strive hard by overcrowding, and by their untidy, filthy habits to poison themselves, but they do not often succeed. If there were only a foul drain and a putrescent dust-bin they would more often achieve what seems to be their object. But the drains, even if out of order, are outside the houses and not under the living- and cooking-room, as I have often found in London and elsewhere. As for the dust-heap, the unauthorised rubbish deposit, the scavengers are too active, and it has not time to grow to dangerous dimensions. Of course, it is all very lamentable, very horrible, and sometimes quite picturesque. We have the poetry of squalor, the fascination of that which is sinister. It is all good subject matter for the realistic artist, for a lay newspaper, for the descriptive portions of a novel with a purpose. Some good word-painting could be done in describing the hovel homes of the workers in the vale of martyrs. But when it comes to technical details, then it must be confessed that these slums are more fortunately situated than is usually the case with slums. With some exceptions of course, they have more air, more light, are more free from the risks arising from faulty drainage than is the case with the slums in many, perhaps in the majority, of the large towns. In consequence of the industrial development the overcrowding is exceptionally prevalent, and this is the principal and most pressing danger. The most striking structural abomination is the "under-and-over" house. This is, indeed, a great and undoubted evil which is special to these mountainous parts of the country. But no one attempts to defend such dwellings, and if a few still remain it is simply because there is such an acute house famine. Thus, and from whatever point of view the question is considered, the conclusion is always the same—namely, that a great number of very cheap houses must be built, and this must be done at once.

*(To be concluded.)*

## MANCHESTER.

**(FROM OUR OWN CORRESPONDENT.)**

*Ladies' Public Health Society.*

THE Ladies' Public Health Society plays an increasingly important part in influencing the public health of Manchester, more especially as regards poor women and children. It has budded off, it may be said, from the Manchester and Salford Sanitary Association, and now has been so far approved of by the municipal authorities that the Manchester women health visitors of the society are paid by the corporation, and they and the lady visitors work in conjunction with

the medical officer of health. The annual meeting of the society was held in the Lord Mayor's parlour, the Lady Mayoress being in the chair, on Jan. 27th. One interesting item in the report had reference to the work of the Mothers' Guild. It was found that many poor women, either before or after confinement, suffered in health, and their offspring also, from insufficient nutritious food, and it was determined to do something to help them by providing one good meal a day, for which in most cases payment was made. During last year 9397 dinners were provided, 8901 of them being paid for and 496 being given. The effect of this one good substantial meal on the health of mothers and babies was noticeable. Intemperance, a foe directly and indirectly injurious, they always had to fight, for it was a cause of much distress. But one of the greatest difficulties to contend with was the wonderful ignorance of the women, especially of the younger ones, who have had all the advantage apparently that they were able to extract from our system of compulsory education. A school for mothers, therefore, had been opened in Manchester, and was doing good work. For the first two years the society had given £50 a year towards its support. The medical report of the Mothers' Guild shows that during the year nearly 250 babies under the age of one year were brought to the guild for the first time, and on an average between 20 and 25 babies had attended every Thursday afternoon for the weekly weighing. A great part of the work of the society is voluntary, and the Bishop of Manchester, in moving the adoption of the report, touched approvingly on the combination of voluntary and municipal effort. In seconding the motion, the Mayor of Salford said, "It was distressing that there were young women who did not know how to take care of their babies, or how to make a home." This society deserves success, and it will not be to the credit of Manchester if it languishes for want of help.

*Coroner and Medical Man.*

There was what the reporters call "a breezy passage" a few days ago at an inquest at St. Helens between Mr. Coroner Brighouse and Mr. F. P. Bassett regarding the registration of a child's death. It cannot be said that these "breezes" are always the fault of either one side or the other, but they are too frequent and do not reflect credit on the coroner's court. In this instance the coroner blamed the medical man for causing the parents to be "put to additional sorrow and the annoyance of an inquest, and explained that Dr. Bassett, instead of giving a death certificate could, if he thought fit, have expressed the opinion that the death was one from natural causes." Mr. Bassett said he could not give a death certificate as he did not precisely know the cause of death. The verdict was "Death from natural causes," and the jury said they "did not think the doctor had acted with any ill-will." The coroner seems to have been a little ruffled in temper, for "he did not think all the trouble would have been caused if there had been an exercise of common-sense." Mr. Bassett, however, held his ground, and concluded by saying: "If you will allow me to say so, I have acted according to law, and I shall always act in the same way." If the law is bad it should be altered, but as long as it is law a medical man should not be blamed for obedience.

*New Altrincham Hospital.*

An isolation hospital, built by the urban district council at a cost of £12,000, was opened about a week ago in Dunham-Massey, Altrincham. Dr. Meredith Young, the medical officer of health of Cheshire, congratulated the council on the completion of "an up-to-date, well-designed, and well-equipped hospital." They wanted to know, he said, whether the hospital was going to give the sufferer a greater chance of getting better than in the home, and whether those in the same house or the same street were going to have a better chance of escaping possible illness and possible death. He was able to assure his audience, from his long experience, that the hospital most positively offered them at least ten times the chance that the ordinary home did.

*Overcrowded Infirmary.*

Almost every charitable institution suffers either from indigence or overcrowding, and after a fairly successful year as regards funds the Rochdale Infirmary has to complain of the latter. At the annual meeting of the infirmary workmen's committee a former secretary of the institution urged strongly the need for making early extensions. He said: "The operating theatre was a disgrace to Rochdale, and the infirmary itself was frightfully overcrowded. More beds were urgently needed." It is to be hoped that Rochdale will rise to the occasion.

*Slums at Knutsford.*

It comes rather as a shock to learn that Knutsford, the Cranford of Mrs. Gaskell's story, should be anything but romantically clean, pretty, and sweet swelling. Yet it seems that some of the housing conditions in the place are shocking. A case of child neglect was brought up and the evidence showed abominable overcrowding. The place had only two rooms, and they were occupied by 15 people, adults and children. The magistrates made the following comment: "The bench think it desirable to say that they cannot understand how it is that such a state of things as this has been allowed to continue in our midst for so long. The local authority has been considerably to blame in not rectifying this state of affairs at a much earlier period." This rebuke does not seem undeserved.

*Water-supply of Ashton-under-Lyne.*

Northern towns which obtain their water-supply from moorlands have to be very watchful as to contamination by lead, not so much from the water before it reaches the lead pipes in the houses as after that from the action on the lead of the slightly acid water. Ashton has been inquiring into the state of its water-supply with satisfactory results as to the cold tap water, no lead being found, though two samples showed slight acidity. With the hot water it was different. Three out of six samples of the latter "showed a marked quantity of lead, which was apparently dissolved from the unions and joints." This is, of course, highly dangerous. Dr. J. W. Talent, the medical officer of health, pointed out that those who drank from the hot water taps ran a decided risk of lead poisoning, and that the practice was highly dangerous. The results of the tests are to be sent to the Local Government Board. The hint as to the effect of hot water increasing the risk of lead poisoning may be taken by many places besides Ashton-under-Lyne.

Jan. 24th.

## BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

*The Late Lord Winterstoke.*

ON Hospital Sunday Lord Winterstoke died, at the age of 80 years, at his house at Blagdon, on the northern face of the Mendip Hills. There is scarcely a feature of the progress of modern Bristol with which he has not been identified and few philanthropic and educational undertakings which have not enjoyed his support in the form of energy, common-sense advice, and liberal contribution. Here it will be enough to recall his association with the University of Bristol and the General Hospital. He was a Pro-Chancellor of the former, and as such formally opened the new wing not many weeks ago. Up to the date at which the University received its Charter his contributions amounted to £35,000. The Art Gallery which he gave to his native city at a cost of £40,000 adjoins the University, and may ultimately become the art school of the University. He was a vice-president of the General Hospital, and not long ago gave £5000 towards the cost of the new buildings which the committee hopes to put up shortly; this was indeed his last public benefaction.

*Hospital Sunday in Bristol.*

On Sunday, Jan. 29th, the Lord Mayor's annual appeal for subscriptions in support of the medical charities of Bristol was issued through the medium, and with the help, of the various places of worship. At the Cathedral service in the morning the Lord Mayor and corporation were present, with the Vice-Chancellor and other representatives of the University, and representatives from the hospital committees and staffs, including the president and chairman of committee of the General Hospital (Mr. Joseph Fry and Mr. Herbert M. Baker). An appropriate sermon was preached by Archdeacon Robeson, and the collection, like others taken throughout the city, was devoted to the Lord Mayor's fund. The facts upon which the appeal is based were summarised on a printed slip distributed throughout the city as follows: The total number of patients treated in the year by the four

chief hospitals (the Royal Infirmary, General Hospital, Children's Hospital, and Eye Hospital) was 109,000; the ordinary income of these institutions amounted to £33,200, and the ordinary expenditure to £39,700. If it was not for the hardness of heart engendered by the annual repetition of such statements, these facts would surely strike the public as deplorable. The perpetual insolvency is, of course, sufficient evidence of the unsatisfactory results of the present haphazard system of medical relief; to this is added the appalling fact that the hospital committees claim with pride to have provided free treatment for more than a quarter of the population of the city. Of course, deductions must be made from the total of 109,000, which includes renewal of treatment by renewal of hospital notes given to patients already under treatment and counted thereupon as new patients; but the total does not include the patients who have been treated by the Bristol Dispensary, the Eye Dispensary, and other smaller institutions. For this tremendous overdraft upon their resources the Bristol citizens have to thank the want of coördinate control, which allows the two larger hospitals to compete with each other in the number of people they can attract to their out-patient departments for treatment. In no city in the kingdom does the hospital system more urgently require overhauling and subjecting to some one supreme authority by whom the relations of the various institutions to each other might be determined and fixed. There was a chance of such an authority being created when the question of a King Edward Memorial Fund was under consideration, but this chance was thrown away.

*A New Games Field for the University of Bristol.*

Mr. George A. Wills has given £4000 to the University for the acquisition of a 12-acre field about two and a half miles from the University buildings at Coombe Dingle, a suburb on the north-western boundary of Bristol. The enclosing and laying-out of the ground will cost about £1000, and the pavilion and dressing-rooms another £1000. In the laying-out of the ground the advice of the head groundman at the Gloucestershire County Cricket Ground, Ashley Down, is being followed. It remains for the University Council to ratify the proposals as to the exact plans to be adopted, and the work of levelling, &c., will then be proceeded with.

*The Red Cross Society in Bristol.*

The members and supporters of the Bristol branch of the Red Cross Society recently held a meeting at the Victoria Rooms, at which satisfactory progress was announced. Over 250 persons have applied to join the voluntary aid detachments, so that it has been possible to form three women's detachments and one of men. Additional detachments have been promised by the Clifton Ladies' Club, by the employees of Messrs. E. W. Savory, Limited, art printers, and by the inhabitants of the suburbs Henbury and Westbury-on-Trym. Other firms have signified their willingness to undertake the training necessary for the formation of detachments. Co-ordination with the St. John Ambulance Association has proved possible in Bristol, so that here, at least, there will be no waste of energy from overlapping of organisations. The committee of the Bristol Royal Infirmary has offered the War Office the use of its premises as a base hospital of 520 beds, the accommodation which will, it is said, be provided by the projected extension of the infirmary if the Nurses' Home be included. A large general committee has been formed, with the Duchess of Beaufort as president.

*Death of William Andrew, M.B., C.M. Edin.*

Dr. W. Andrew of Launceston died on Jan. 25th, in his sixty-second year. The deceased, who graduated as M.B. and C.M. of Edinburgh in 1873, had been in practice for many years in Launceston, where he was extremely popular and highly esteemed. He took a great interest in all municipal matters, was mayor of Launceston on two occasions, and at the time of his death was an alderman of the borough. He was a staunch Churchman, and for the past 23 years had been vicar's warden of St. Mary Magdalene, one of the most beautiful churches in Cornwall. He was a prominent Freemason. He had a large practice in Launceston and the district, and was medical officer to the local dispensary. Dr. Andrew was unmarried. He will be greatly missed in Launceston, where his cheery manner and generosity had endeared him to all classes of the inhabitants.

*The Royal United Hospital, Bath.*

The annual meeting of the subscribers to the Royal United Hospital was held at the Guildhall, Bath, on Jan. 27th, under the presidency of the mayor. The medical report was satisfactory, but the financial statement showed that although most careful economy had been practised the deficit balance on the working of 1910 amounted to £1838.

*New Isolation Hospital in Somerset.*

At a meeting of the Radstock urban council held on Jan. 22nd it was decided to erect an infectious diseases hospital for the Clutton rural council and the Midsomer Norton and Radstock urban councils. The cost of the building will be about £7000. The council also determined to petition the Somerset county council to make a joint hospital area of the three districts concerned.

*The Yeovil and District Hospital.*

At the annual meeting of the subscribers to this institution held on Jan. 26th a deficit of about £62 was reported for the year. At the suggestion of a member of the committee the money was subscribed by those present and the debt wiped off.

*Amalgamation of Health Appointments.*

At a meeting of the Swindon (Wilts) town council held on Jan. 18th the health committee recommended that the medical officer of health (Mr. F. E. Streeten) should for the future devote the whole of his time to the duties of the office, in combination with that of medical inspector of schools. The committee made a proviso that Mr. Streeten should continue to hold the appointment of medical superintendent of the infectious diseases hospital and also that of medical officer of health for the Highworth rural district. The town council, after some discussion, adopted the proposal.

*The Care of Epileptics.*

At a meeting of delegates from the Poor-law unions of Dorset, which was held at Dorchester on Jan. 17th, it was resolved to approve the principle of removing epileptic patients and feeble-minded persons who were resident in workhouses to a suitable institution, to be controlled by a committee appointed by the unions of the county.

*"A Medical Account to be Paid within 12 Hours."*

At the Tavistock (Devon) county court on Jan. 21st Dr. W. R. Griffin of Tavistock sued Mr. M. Howick, a traveller, for 50*s.* for professional attendance upon his son. Defendant paid £1 into court, and contended that this sum was sufficient for the services rendered. His honour (Judge Lush Wilson, K.C.) gave judgment for Dr. Griffin, and as the defendant did not permanently reside at Tavistock ordered that the amount should be paid within 12 hours.

*The Duties of Public Vaccinators.*

At the last meeting of the Tiverton (Devon) board of guardians it was reported that one of the public vaccinators had not sent any certificates of successful vaccinations since October, 1910, and when written to on the subject by the guardians had not replied to the communication. After some discussion it was decided to inform the Local Government Board of the matter.

*Medical Relief and Old Age Pensioners.*

At the last meeting of the Axminster (Devon) board of guardians it was decided that when old-age pensioners applied for medical aid each individual case should be treated on its merits.

*The Exmouth (Devon) Dispensary.*

At the annual meeting of the subscribers of the Exmouth Dispensary, which was held on Jan. 25th, the following members of the honorary medical staff, whose term of office had expired, were re-elected:—Consulting Physicians: J. W. Hodgson, M.D., C.M. Aberd., M.R.C.S. Eng.; and R. S. Thomas, M.A., M.D., M.C. Cantab., L.R.C.P. Lond., M.R.C.S. Eng. Consulting Surgeons: J. T. Langley, M.R.C.S. Eng., L.S.A., and J. Cock, M.R.C.S. Eng., L.R.C.P. Lond. Medical Officers: G. L. Thornton, M.A. Cantab., M.R.C.P. Lond., M.R.C.S. Eng.; O. Eaton, L.R.C.P. Lond., M.R.C.S. Eng., D.P.H. Camb.; and G. H. Hanna, M.B., Ch.B. Edin.

Jan. 31st.

# WALES.

(FROM OUR OWN CORRESPONDENT.)

*The Water-supply of Borth.*

THE inhabitants of Borth, on the Cardiganshire coast, have prudently decided to ensure for themselves a sufficient supply of water. The town has a resident population of about 800 persons, and in the summer-time that number is nearly doubled. The existing supply is obtained from springs, the water from which is impounded in a small reservoir with a capacity of 40,000 gallons. It is proposed to abandon this reservoir and construct another to hold 664,000 gallons, at a cost of £3000. Mr. John James, one of the medical officers of health of the Aberystwith rural district, in which Borth is situated, is of opinion that the water has no plumbo-solvent action, and that it will not require to be filtered.

*Public Health in Towyn.*

The estimated population of Towyn, Merionethshire, is 3980. Between 1891 and 1901 there was an increase in the population of 443 persons. In his annual report for 1910, the medical officer of health, Mr. E. Lewys-Lloyd, has recorded the very low birth-rate of 14·4 per 1000 of the population, and a death-rate from all causes of 12·1 per 1000. The death-rate from phthisis was 1·5 per 1000. In the past ten years every seventh death registered has been due to some form of tuberculous disease. A scheme of voluntary notification of cases of phthisis is in force in the town, and disinfection of rooms occupied by consumptive persons is freely offered by the district council, the offer only rarely being refused.

*Damages for Slander awarded to a Medical Officer of Health.*

At the recent Carmarthenshire assizes the medical officer of health of Carmarthen, Mr. L. M. Bowen-Jones, was awarded damages to the extent of £100 in an action which he brought against a member of the Carmarthen town council. The cause of action was apparently trivial, and referred to some building stone which Mr. Bowen-Jones had obtained from the corporation, and which the town councillor alleged had not been paid for. In spite of the assertion of the borough surveyor that the stones had been paid for, the statement was repeated and persisted in that no payment had been made; so that, to quote the words of Mr. Justice Lush, who tried the case, Mr. Bowen-Jones could not sit down without investigation after being called a thief. As already intimated, the jury gave a verdict in his favour.

*Water-supplies of South Wales Colliery Districts.*

Three years ago the corporation of Merthyr decided by a majority of 9 votes in a council meeting of 29 members to promote a Bill in the 1908 session of Parliament, having for its object the construction of an additional reservoir, at a cost of some £350,000. When the scheme was placed before a meeting of the ratepayers, however, it was strenuously opposed, and a resolution of disapproval was carried by an overwhelming majority. In these circumstances the Bill was not proceeded with. Three years later—that is to say, on Jan. 11th last—a Bill containing almost identical provisions to that of 1908 was submitted to a town meeting, and on that occasion received what was practically the unanimous approval of the ratepayers. The reason for this change of opinion is not far to seek. It is due to the fact that the sanitary authorities in the Rhymney valleys are promoting a Bill in the coming session for the constitution of a water board having power to purchase two existing water undertakings in the valley, and by throwing a dam across the river Taf Fechan in Brecknockshire to construct a reservoir in precisely the same position as that proposed by the Merthyr corporation, which is above the existing reservoirs belonging to Merthyr. The area of supply of the new board would include the whole of the urban districts of Rhymney and of Gelligaer, with portions of the urban districts of Caerphilly and Bedwellty. The need for an increased supply of water in the Rhymney valley is very great, and there is little doubt as to that need being recognised by Parliament. That the need can be met by impounding the waters of the river Taf Fechan is admitted, and so long as the inhabitants of the valley obtain the water it is of little consequence by whom the works are carried out, though in all probability a joint board representing the Merthyr corporation and the authorities in the Rhymney valley would be the proper body to be entrusted with it.

# SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*Eye, Ear, and Throat Infirmary of Edinburgh.*

IN the report of the Eye, Ear, and Throat Infirmary of Edinburgh for 1910 an account is given of the history of the institution. It originally existed as the Eye Infirmary of Edinburgh, founded in 1834. In 1883, when departments were added for ear, nose, and throat cases, the name of the institution was changed to that of the Eye, Ear, and Throat Infirmary of Edinburgh. The institution not only carries on out-patient work, but accommodates in the wards patients requiring operative treatment. The premises consist of two flats in Cambridge-street. During 1910 a larger number of patients had been dealt with than in any previous year. During the year 5311 new patients had been seen, and of these 132 had been treated in the wards as in-patients. The increase in the cases is mainly due to the large number of children from the Board schools sent in consequence of their parents having been notified of eye defect. The work thrown on the medical officers of the eye department was very great and deserved special recognition. The ordinary expenditure had been £416, having exceeded the ordinary income of £321 by £95.

*Edinburgh Medical Missionary Society.*

The annual meeting of the Edinburgh Medical Missionary Society was held on Jan. 26th, Dr. J. W. Ballantyne, president of the society, being in the chair. In the report statistics were given for the last ten years of the society's work. In that time 107,623 cases had been dealt with at the Livingstone Dispensary in the Cowgate, and 2020 patients had enjoyed a fortnight's stay at the Convalescent Home in Duddingston. During the decade the ordinary income amounted in all to £44,458, an average of £4445 17*s.* per annum, while the ordinary expenditure had amounted to £51,488, an excess over the ordinary income averaging £703 per annum. This had been met by drawing on the extraordinary income. The total income for 1910 was £5592, including legacies. After the adoption of the report the directors were re-elected on the motion of Dr. J. O. Affleck, seconded by Professor A. Crum Brown.

*Installation of Lord Rector of Glasgow University.*

Lord Curzon of Kedleston was last week installed Lord Rector of Glasgow University. The ceremony took place in St. Andrew's Hall, in presence of a large number of undergraduates and of the public. Lord Curzon received the honorary degree of LL.D., the capping ceremony being performed by the Vice-Chancellor, Principal Sir Donald MacAlister. The Lord Rector then delivered a most impressive address, taking as his subject, "East and West: a Retrospect and a Forecast." Afterwards he was entertained at luncheon in the University. In proposing the toast of "The University," his lordship dealt with the expansion in the conception and ideals of the universities that had taken place during the past fifty years.

*Glasgow Maternity Hospital Appointments.*

The directors of Glasgow Maternity Hospital determined some time ago to open a gynæcological wing in that institution, and at a meeting held last week it was decided that Dr. Robert Jardine and Dr. Samuel J. Cameron should be elected to the senior appointments. Dr. Jardine is professor of midwifery at St. Mungo's College and is at present a member of the obstetrical staff of the Maternity Hospital. He is an examiner in midwifery to the Scottish Conjoined Board and also holds a similar position at the Victoria University, Manchester. Formerly he was an examiner at the University of Glasgow. Dr. Cameron is a graduate of Glasgow University and assistant to the Regius professor of midwifery at the University.

*A Medical Man and the Sale of Food and Drugs Act.*

A Glasgow medical man was recently charged under the Sale of Food and Drugs Act with having sold, through an assistant, 3 ounces of sweet spirit of nitre that did not come up to the standard of 1·75 per cent. of ethyl nitrite required by the Pharmacopœia. The accused, who was defended by Mr. William Findlay for the Medical and Dental Defence Union, was acquitted.

*Montrose Asylum Board and the New Charter.*

The special committee of the Montrose Asylum and Infirmary Board, appointed to consider the demands of the Forfarshire District Lunacy Board and parish councils of Forfarshire and Kincardineshire for representation on the board of management, handed in its report at a special meeting of the managers held last week. It recommended that the board should agree to a conference, and that a special committee should be appointed to attend it and report to the board. Subsequent to the committee meeting at which this decision was arrived at, a letter, in reply to one by the clerk to the managers, requesting information as to the objections taken by the memorialists to the scheme submitted by the board, was read from the Secretary for Scotland, in which he replied that from resolutions submitted to him by these bodies after consideration of the proposal for a new charter put forward by the managers of the asylum, he gathered that the main points of difference were as regards: (1) The relationship between the asylum and the Montrose Infirmary and Dispensary; (2) the constitution of the board of management of the asylum. If their committee thought it necessary to ascertain, more particularly at the present juncture, the views of the district lunacy board and parish councils, Lord Pentland would suggest that they should communicate with Mr. R. Freer Myles and Mr. W. K. Macdonald, who acted for these bodies respectively; but it appeared to his lordship eminently desirable, in the event of a conference such as was under consideration of their committee, that parties should enter upon the discussion of the points as little hampered as might be by antecedent proposals or resolutions. The recommendation of the special committee that a conference should be held was agreed to.

*The University of St. Andrews and the Inclusive Fee.*

At a meeting of the University Court of St. Andrews, held on Jan. 21st, there was submitted a memorandum of the deliberations of a conference of representatives of the University Courts of the four Scottish Universities, upon the proposed institution of inclusive or composite fees, to be uniform for a recognised course of study for the same degree throughout the Scottish Universities, in fulfilment of the condition attached by the Treasury to the additional grants voted to the Scottish Universities. The Court directed intimation to be made to the Treasury that it had accepted the principle of an inclusive fee, and had generally approved of the memorandum and the recommendations of the conference.

*Proposed New Arbroath Infirmary.*

A meeting was held on Jan. 23rd of the Arbroath Infirmary directors. A report was read by Dr. Macintosh, medical superintendent of the Western Infirmary, Glasgow, who has been appointed by the building committee to examine the Arbroath Infirmary. The important alterations and additions recommended in the report would involve an outlay of at least £6000, and the opinion was expressed that it would be better to erect a new building altogether. An architect was appointed by a ballot vote to advise the directors in the circumstances, and it was remitted to him to bring up a report as to what was advisable to be done.

*Aberdeen Students and the Rector's Carriage.*

A mass meeting of Aberdeen students was held on Jan. 26th to consider the position with regard to the smashing of Mr. Asquith's carriage on the occasion of the rectorial address. Mr. Trail, the owner of the vehicle, has offered to accept £25 as settling the whole claim, and after a statement by the President of the Students' Representative Council, it was agreed that the students should be asked to contribute that sum.

Jan. 31st.

# IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Treatment of Juvenile Criminals.*

IN a presidential address to the Statistical and Social Inquiry Society of Ireland last week Lord Justice Cherry dealt with the modern treatment of young criminals. Since 1906 a Borstal institution has been in existence in Clonmel prison, and last year the entire prison was given over to Borstal work, the ordinary prisoners being transferred elsewhere. Prisoners from all over Ireland are now brought to Clonmel if sentenced to detention in a Borstal institution or to ordinary imprisonment of sufficient duration to give hopes of successful reformatory treatment. The results of the work in Clonmel have been very satisfactory. Of youths discharged under licence by the powers of the Prevention of Crimes Act, 1908, not one has been brought back for further detention. Lord Justice Cherry protested against short sentences for children. A short sentence, he said, had no punitive effect on a child, only tending to familiarise him with the inside of a prison. If it were necessary to place a child under detention he should be given a sufficiently long sentence for the Borstal system to have a chance of being efficacious.

*Action for Fees.*

Sir Christopher Nixon last week sued two ladies for £30 9*s.* for services rendered, journeys made, and work done at their request, and damages for breach of contract. As a consequence of a motor accident the ladies sued the owner of the car for damages. Their solicitors had arranged with Sir Christopher Nixon to examine them and testify in court. The fee now disputed was 25 guineas for attendance and testifying in court, as arranged with the solicitors. Sir Christopher Nixon having attended court as requested on a certain day and hour, found that the case had been settled. The solicitors declined to pay the fee on the ground that he had not actually given evidence. It was also contended that when a medical man had examined a person whose condition subsequently became a question in court, he could be compelled to attend and testify for the fee laid down in the schedule. The Recorder gave judgment for the full amount, holding that there was an express contract between the parties, of which Sir Christopher Nixon had performed his part so far as he had not been prevented by the other parties, and strongly criticised the solicitors for refusing to pay the fee.

*Proposed Reforms in the University of Dublin.*

The Senate of the University of Dublin last Saturday by a large majority approved the proposed reforms in the constitution of the University Council—viz., that the Council should have a more representative basis than heretofore, and in particular that direct representation should be given to the teachers in the professional schools. The School of Physic is to have the election of two members, the entire Council to consist of 19 members.

*"Corrected" Death-rates.*

IN THE LANCET of Jan. 21st, p. 189, Sir John Moore drew attention to a change in the classification of diseases recently adopted by the Registrars-General of the three divisions of the Kingdom. Another change has been made by the Registrar-General for Ireland in his weekly returns of births and deaths. Formerly the actual death-rate for the Dublin registration area was stated, in addition to a corrected rate which omitted the deaths in public institutions of persons admitted from without the area. The actual rate is now omitted, thus preventing a true comparison with former years, and unduly exaggerating the improvement in the state of public health in Dublin.

*Spiddal Water-supply.*

At a recent meeting of the Galway rural council a report was read from Mr. W. P. Kirwan, medical officer of health, concerning the water-supply of Spiddal, a seaside village near Galway. It stated that Spiddal was supplied from a river of peat water, into which dead animals were thrown, filling it with decaying matter. No wonder that Spiddal is a hot-bed of typhoid fever, to which disease more than one medical man has succumbed within the past ten years.

*Ballycastle Dispensary.*

Dr. Daniel Boylan was, on Jan. 24th, unanimously elected medical officer of the Ballycastle district at a salary of £155, rising by four increments of £7 10*s.* to £185, with registration and vaccination fees, and also £20 as medical officer of health. Dr. James McIlroy, the retiring dispensary medical officer, who has had 43 years' service (21 of them at Castlequarter), was granted, subject to the approval of the Local Government Board, a retiring annual allowance of £135.

*The Queen's University of Belfast.*

At a mass meeting of students of Queen's University, Belfast, on Jan. 25th, resolutions were unanimously passed urging that the time has come for the acquisition of athletic grounds, and appealing to the sympathetic consideration of the Senate. About four years ago the students, aided by their friends and by the citizens, raised £5000 for the purchase of an athletic field, but since then nothing definite has resulted. Inasmuch as just now the various committees of the Senate are planning innovations and improvements in building equipment, &c., in connexion with the University, a deputation of students was appointed to wait upon a joint finance and athletic field committee of the Senate.

*Forster Green Hospital for Consumption.*

At the fifteenth annual meeting of the friends of this hospital on Jan. 26th it was reported that 269 patients (38 more than in the previous year) had been admitted during 1910, but the average duration (12 weeks) of their treatment was rather shorter. Including those remaining from last year, 337 cases were treated during the year. Twice as many cases in the incipient stage were admitted during 1910 as in 1909. The medical staff report two grave defects: First, the admission of advanced cases which, after a time, go home, where they are a source of danger, to die; and, secondly, that patients who have greatly advanced on the road to recovery are compelled to leave and return to work, whereby many of them relapse.

*Memorial to the late Dr. W. B. McQuitty.*

A very largely attended meeting—all classes in the community being represented—was held in the City Hall, Belfast, on Jan. 26th, for the purpose of considering the best means of perpetuating the memory of the late Dr. W. B. McQuitty. The Lord Mayor (Mr. R. J. McMordie, M.P.) presided. On the motion of Sir John Byers, seconded by Mr. James Davidson, chairman of the board of management of the Royal Victoria Hospital, and supported by Sir Peter O'Connell, D.L., President of the Ulster Medical Society, it was unanimously resolved that there should be a memorial to the late Dr. McQuitty. Dr. J. J. Adams, J.P. (coroner for East Antrim) moved, and Mr. J. McAlery seconded, the appointment of a representative committee to carry out the object of the memorial, with Mr. J. G. Turner, Northern Bank, Belfast, as treasurer, and Dr. John Campbell, Dr. W. M. Killen, and Mr. C. J. Milligan as secretaries. The memorial will probably take the form of a scholarship in clinical medicine at the Royal Victoria Hospital, with which Dr. McQuitty was so long associated.

*The Union Workhouse, Belfast.*

From the report of the inspectors of the Local Government Board on the Belfast Union Workhouse, which has just been published, it is satisfactory to find that in the Belfast Workhouse and in the Whiteabbey Sanatorium the total number of inmates—3437—was smaller last year than for more than six years past, due largely to trade improvement in Belfast. The inspectors think that the children in the workhouse, though well looked after, would be more likely to become useful members of society if removed from the atmosphere and associations of a large mixed workhouse; also that the guardians should weigh the wisdom of allowing expenditure on out-door relief to continue increasing at the high rate of the past five years. At Whiteabbey Sanatorium, the inspectors say, "everything possible is done by the Abbey staff to promote the well-being of the patients."

Jan. 31st.

DEATH OF A GLOUCESTERSHIRE CENTENARIAN.—Mrs. E. Parnell of Olveston, who recently attained the age of 100 years, died on Jan. 26th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

*Hygienic Dwellings.*

AT a recent meeting of the Society for Social Medicine Dr. Flesch, a town councillor of Frankfort, communicated an interesting report on the dwellings built by the society for the better housing of the working classes. He said that since the year 1891 the society had provided accommodation for 5617 persons in 1201 houses. The house-rent was from 25 to 30 per cent. less than in private houses. Each block had a hall for the general use of the residents, a reading-room, a library, playgrounds for children, and a crèche. Coals and several kinds of provisions, including potatoes, were kept in store by the society, and the tenants were allowed to buy those articles at wholesale prices, the society making no profit out of the sale. By a mensual contribution of about 3½*d.* the tenants became entitled to the services of a trained nurse in cases of sickness or lying-in, only a penny (10 pfennig) a day being then charged for nursing. The house-rent must be paid in advance, or otherwise the society had the right to give the defaulting tenant notice to quit, and the same was the case when a joint application was made by several tenants to the effect that a certain individual should not be allowed to remain. Special medical interest attached to the fact that the mortality of the tenants was considerably less than that of the general population of the city; during the past 11 years for which the society has worked the general mortality of Frankfort had decreased by 3 per cent., and that of the tenants of the society's houses by 6 per cent. It might be supposed that this was due to the better financial position of the tenants, who did not belong to the poorest classes of the community but rather to the general working population; it was, however, remarkable that when a new block was opened the mortality of the incoming tenants was at first greater than it afterwards became when they had lived for some time in their new quarters. The good hygienic conditions of the society's houses seemed, therefore, to have a good influence on the mortality. The principal decreases of the death-rate were under the heading of tuberculosis, in which it was 1·85 per 1000 as compared with 2·15 per 1000 in the city, and under the heading of infantile diarrhœa, in which it was 0·95 per 1000 as compared with 1·55 per 1000 in the city. The lower death-rate was caused firstly by the good hygienic condition of the society's buildings, and secondly by the low rent, as the money saved in this way was spent on better food. Another good effect of this economical housing was that mothers did not require to go out to work and were therefore able to give more attention to their children. In conclusion, the speaker said that the erection of cheap and wholesome dwellings was one of the pillars of modern hygiene.

*Pyrexia in Malignant Growths of the Kidneys.*

At a meeting of the Berlin Surgical Society Professor Israel read a paper on the occurrence of pyrexia in patients suffering from malignant growths of the kidneys and the suprarenal capsules. He said that this symptom had hitherto been rather neglected by observers, but that it was not so rare as had been supposed. Of 146 cases of malignant growths of the above organs operated on by him, 12—i.e., 8·2 per cent.—were associated with pyrexia. It was essential to be aware of this fact in order to avoid errors in diagnosis; he mentioned a case in which a malignant growth attended with pyrexia was supposed to be a spleen enlarged by malaria; in another case which he quoted the high temperature was attributed to latent pulmonary tuberculosis, and the patient was sent to a sanatorium. The pyrexia might occur at different stages of the disease; it might be present in the initial stage either simultaneously with the first symptom of the growth or even before such symptoms have become obvious. In some cases it made its appearance together with other symptoms at any stage of the disease, and in a third category it was observed only in the last stage where cachexia and metastases were present. The pyrexia might be of either the remittent or the intermittent type, and might occasionally last for several months. Sometimes it resembled relapsing fever and sometimes it was in association with hæmaturia, either preceding or following it. Professor

Israel also discussed the influence which an operation performed for the malignant growth might have on the pyrexia. He quoted 12 cases, but excluded five of them from the computation, because in two there was no pyrexia at the time of the operation and three of the patients died a short time afterwards. Among the remaining seven cases there were five in which no pyrexia occurred after the operation, whilst in two the patient's state was the same as before. In the latter two cases the operations were incomplete, because in one of them the growth had partly penetrated into the vena cava, and in the other a cluster of glands in connexion with the large vessels had to be left behind. It must therefore be concluded that the pyrexia depended on the presence of the growth, and this view was supported by the fact that pyrexia sometimes occurred when metastases were developing, or in cases not operated on, when a tumour suddenly commenced to grow rapidly. The cause of the pyrexia was quite uncertain; it neither depended on the histological structure nor on the size of the tumour, but only on the degree of malignancy, and the prognosis of a growth associated with pyrexia was, as a rule, decidedly unfavourable.

Jan. 30th.

## BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

*Arsenobenzol (Salvarsan) in Hungary.*

As soon as it became known in Hungary that Professor Ehrlich had introduced a new remedy for syphilis large numbers of medical men travelled to Frankfort for the purpose of seeing him in his laboratory and congratulating him warmly. From Frankfort they went to Berlin to see Professor Wechselmann, who was the first to adopt the treatment of syphilis with arsenobenzol, and when they returned home the daily newspapers, which had in the meantime been publishing long accounts of marvellous recoveries obtained with the new treatment, turned them into heroes. When these gentlemen resumed practice after their visit to Germany they were offered high fees by patients—some of them suffering from syphilis and some not—for injections of arsenobenzol. Several of the medical men took advantage of these offers and charged exorbitant sums for giving such injections, a course which has been very sharply criticised by the professional journals as a serious offence against medical etiquette. The pharmaceutical chemists, seeing how much the public were interested in the subject, also provided themselves with hundreds of doses of the new remedy when it was put on the market under the name of salvarsan, about 25,000 doses being ordered for the whole of Hungary. It was therefore not surprising that the medical journals were offered far more articles than they could possibly publish, all containing in some form or other "personal experiences with Ehrlich's remedy." Among those who took up the matter from a scientific point of view, Professor Jörök, Professor Havas, Professor Selley, and Dr. Spatz, surgeon-major in the Hungarian National Army, were prominent. Professor Emile Grosz was the first among the investigators who called the attention of the profession and also that of Professor Ehrlich himself to the danger of dissolving arsenobenzol in methylated spirit. Shortly before the discovery of arsenobenzol Professor Grosz had even written a long memoir on the harmful action of methylated spirit on the optic nerve in connexion with the numerous cases of poisoning in Hungary with methylated spirit. At present the majority of practitioners use the neutral suspension method and are administering the drug subcutaneously according to the instructions of Professor Wechselmann. In hospitals the intravenous method is also employed. As for the results in general, articles which were not very loud in praise of arsenobenzol were published as far back as September, 1910. Even one of Ehrlich's most ardent followers ventured to say that he was so little impressed with the efficaciousness of arsenobenzol that he was ordering his patients to continue inunctions with grey ointment. Since the introduction of salvarsan the conviction has become wider that Ehrlich's remedy is not at all superior to either mercury or iodine. Some say that it is to be administered only in malignant cases, and in cases for which mercury is of no use, but these cases are fortunately very scarce. Some days ago Dr. Fekete Gábor published an article embodying several objections to salvarsan arranged under the following heads. 1. First of all, he says that it is uncommonly dear. As its manufacture is neither complicated nor difficult he cannot comprehend why 12 kronen (10*s.*) are charged for it when similar amounts of preparations of that class are sold for 2 kronen or so. 2. The making of the suspension is imperfect and gives a great deal of work to the practitioner; sometimes it is very difficult to neutralise the solution accurately. In preparing the solution a good deal of the salvarsan is wasted because it adheres to the glass rod and to the glass or porcelain of the mortar. 3. Intramuscular and subcutaneous injections are painful, and intravenous injection is dangerous. The first two methods are liable to be followed by local infiltrations which last for six weeks or longer and may even not disappear at all; they may also turn into abscesses or necroses which are very difficult to heal, and have sometimes led to erosions which have had to be repaired by transplantation of skin. 4. The results of the treatment are not at all superior to those obtained with mercury, although he admits that lesions of the mucous membranes heal very quickly. It is only in cases where mercury is of no use and in cases of malignant syphilis that Dr. Fekete Gábor will resort to salvarsan. Another investigator has described some ill-effects of salvarsan. He says that in some of the cases under his care it worked liked a charm as regards lesions of the mucous membranes and the skin, but other symptoms, such as diseased conditions of the bones, the periosteum, and the central nervous system, were not very favourably influenced. In some cases he was induced to repeat the injection. The result was less than in the first instance. In his opinion this fact bears out Darwin's theory of adaptation, according to which the spores and the new generation of spirochætæ might be expected to adapt themselves to the germicidal properties of arsenobenzol and to become more resistant. In such cases the poisonous action of salvarsan might supervene and cause untoward symptoms. In the *Orvosok Lapja* of Jan. 14th Dr. Schmidt asks if syphilitic patients in the hospitals should be treated with arsenobenzol. In Hungary most general hospitals are maintained by the State, and the medical men are allowed to use only official remedies, and these only according to special hospital formularies, where the chief aim is economy as far as it does not affect the chances of the patient's recovery. If a medical man prescribes, either intentionally or from forgetfulness, medicines not included in that formulary then he has to pay their cost out of his own pocket. As salvarsan is not yet on the official list its administration in hospitals is prohibited. Dr. Schmidt maintains that the State would gain by the use of the salvarsan treatment for syphilis, basing his computation on the total number of days spent in the hospital by patients and on the cost of medicines used. He says that up to now a syphilitic patient spends on an average 40 days in the hospital, using 180 grammes of grey ointment and 12 doses of iodine solution, which cost the State about 90 kronen (75*s.*). In view of the fact that treatment with one dose of salvarsan, costing 10*s.*, takes only 20 days, the State would save about 40 kronen (32*s.*) on each individual. The whole of Dr. Schmidt's reckoning is, however, contradicted by Dr. Walko, who says that the arsenobenzol treatment does not render grey ointment and iodine superfluous, because the majority of medical men order the continuation of inunctions even if the patient was treated with salvarsan. Replying to Dr. Schmidt's statement that patients treated with salvarsan make only a short stay in hospital, Dr. Walko says that these patients may sooner or later come back to the hospitals for mercurial treatment just as if they had not been treated with salvarsan at all.

Jan. 23rd.

FIRE AT THE EALING ISOLATION HOSPITAL.—On the evening of Jan. 31st a fire broke out in the western portion of the north block of the Ealing isolation hospital. The roof of the building was entirely destroyed and the other parts of the building were much damaged by smoke and water. The children in the wards were taken to a place of safety, prompt action being shown by the staff in removing the children.

## CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

*The Cholera Epidemic.*

NO case of death from cholera has latterly occurred either among the general public or among the soldiers garrisoned in the city. This, at least, is the official report appearing in all the local newspapers. Whether it is true seems to be doubtful. People in Constantinople are generally afraid to give to the medical authorities notice of a cholera case, making every possible attempt to keep the matter secret. The public here are under the impression, in the majority of instances, that the municipal physicians only aggravate the situation by their unskilful meddling and exaggerated measures of precaution. In some quarters, and that not altogether among the lower classes, there actually exists a belief that it is in the interest of the medical authorities to poison suspected cases in order so much the surer and the speedier to stamp out the epidemic. In these unfortunate circumstances it is quite likely that cases of cholera still occur, but the authorities are not aware of it. Thus, a medical man told me only the other day that he attended this week a genuine cholera case which did not appear in the official report. However this may be, the epidemic can be considered, to all intents and purposes, as having disappeared from Constantinople. But the Minister of the Interior has decided, in conjunction with the municipal and medical authorities, to continue for a long while yet, perhaps throughout the whole winter, all the prophylactic and precautionary measures which have been adopted from the very first. This is a laudable decision, and if consistently and strictly carried out might make it impossible for another cholera epidemic to reappear in the spring, as is the usual experience here with epidemics. The local newspapers speak in laudatory terms of the zeal and sagacity of Talaat Bey, the Minister of the Interior, who presides over the Sanitary Commission. He takes great personal interest in the hygienic well-being of the city. He visits the sources of water-supply to ascertain the state of the canals, as well as the sanitary condition of the aqueducts and lakes. Lately he made a little expedition of this sort, and found that the Dercos water, which supplies a large section of the metropolis, is quite unsuitable for drinking purposes. Necessary measures to improve matters are being taken. Talaat Bey has undoubtedly done very much to stem the progress of the epidemic of cholera. Cold, wintry weather prevailing at the moment when I am writing these lines renders its own great help to all the energetic human efforts.

*Hospital Steamboats.*

The Ottoman Government has decided to purchase a number of hospital steamboats for the transport of soldiers when ill. These steamboats will have all the necessary requisites for an up-to-date medical service. Each will possess a dispensary, bath-rooms, ice factory, wards, &c. Their displacement will be 2000 tons and they will be able to attain great speed.

*New Slaughter-houses.*

I understand that the municipality of the city intends purchasing the free part of the quarter Koutchouk-Vlanga in Stamboul in order to construct a number of spacious slaughter-houses. These will be equipped with all the necessary requisites, will possess a chemical laboratory, a special cabinet for veterinary surgeons, a reservoir for the collection of the blood of the slaughtered animals, depôts for straw and grass, a restaurant, and a coffee-house. It has long been felt that proper slaughter-houses were the great need of a city, where about 2,000,000 cattle are killed annually.

*A New Asylum.*

The *Osmanischer Lloyd* announces that the condition of the asylum for insane people at Scutari being very unsatisfactory, it has been decided to erect a new institution of that kind in San-Stephano. A sum of 50,000 Turkish liras was originally asked for the purpose. This sum, however, has been found insufficient. It is thought that it will require £T120,000 in order to build an asylum of the proper dimensions and with the necessary equipment. To facilitate matters, £T20,000 will be allowed annually from the municipal budget. The plans of the buildings are ready and have lately been submitted for examination to the Council of State.

*Disastrous Earthquakes in Turkestan.*

Distressing details have come from Vernyi, Turkestan, of the disastrous earthquake that lately visited that unhappy Russian province. It lasted for five minutes, and the first violent shock was followed by several others of lesser violence. This earthquake is one of the most calamitous that ever befell Russia. The full extent of the terrible destruction is not yet exactly known. Some idea, however, can already be formed of the enormous loss of human life, of property, and of cattle. Up to now, so say the local newspapers, more than 2000 dead bodies have been found and many hundreds are missing. Some say that the number of the last amounts to 10,000. Many thousands of different cattle, the principal possession of the native population, perished in the earthquake, and a far greater number became victims of the extraordinarily cold weather that was prevailing at the time, of hunger, and of the snow-storms. Many rich families became beggars, many camped in the snow-covered fields, the temperature being about 30° C. below zero, and the death-roll will be heavy if help is not forthcoming. Mothers are unable to feed their children, and the mortality among the latter is appalling. The Russian Government is doing its best to alleviate the crying misery, but its means seem to be limited, for it would be necessary, to begin with, to construct some 100 villages and to purchase cattle for thousands of families. The Tsar has shown great sympathy for the stricken population, mostly Mahomedans, and has sent a large sum from his private purse, and the Tsarina has opened a list of subscriptions. Every offer is gladly accepted—money, clothing, building material of every description, petroleum, flour, &c. Twenty-three years ago Turkestan was visited by a somewhat similar earthquake, but it was not of such a calamitous extent. Help this time is also being sent from different parts of the Turkish Empire.

## UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

*The "Johns Hopkins Idea" in New York Medical Institutions.*

A PLAN to unite the faculty of medicine of Columbia University and the Presbyterian Hospital of New York city has been under consideration for some time, it being proposed to create the same relationship between these institutions as exists between Johns Hopkins University and Johns Hopkins Hospital, Baltimore, Md., with which Professor William Osler was so long connected. This linking of the University with the hospital and the medical school seems to be in the air, for there was recorded in THE LANCET of June 11th, 1910, that the Washington University in that city was, in pursuance of the same idea, to have its own hospitals with the necessary laboratories adjacent thereto. The donation of £300,000 from an anonymous source will certainly hasten the consummation of this union in New York also. The gentleman who acted as intermediary between the anonymous philanthropist and the two institutions has himself offered the sum of £40,000 in addition, and has furthermore proposed to endow and fully equip a surgical pavilion of 150 beds. It is understood that the University, in return for the privilege of making all nominations to the hospital staff, shall meet the expense of all scientific and educational work associated with the hospital. Each institution will maintain its own corporate existence. Those who are appointed as visiting physicians and surgeons to the new hospital will be expected not to occupy similar positions elsewhere. The Presbyterian Hospital had already made plans to build an extension which will adjoin the Rockefeller Institute for Pathological Research.

*Leprosy in the United States.*

Nine lepers were exhibited to the members of the Academy of Medicine on the evening of Dec. 29th, 1910. In an effort to dissipate the prevalent superstitious horror of this disease the nine patients, who included a negro girl, a male negro, an Italian with advanced tubercular leprosy, a Russian, and a Chinaman, were brought to the Academy in the public tramcars, coming from various remote suburbs of the city.

The general tone of the meeting deprecated the hysteria which has arisen through popular ignorance whenever leprosy has come up for public discussion in the United States. Dr. C. W. Duval, of Tulane University, New Orleans, La., who was the first to grow the bacillus lepræ in culture media, described his experiments and what he expected to accomplish with serums in producing immunity. He said that experiments with Japanese mice and other animals showed that the disease was certainly infectious by contact.

*Unauthorised Necropsies.*

Two physicians of Long Island City, a part of the greater city of New York, were recently sued for £2000 damages for performing an unauthorised necropsy on the body of a widow, said to have died from gangrenous perityphlitis. The suit was brought by the children of the deceased and the jury awarded £1600 damages, the action being undefended. This is the first case of the kind ever tried in the United States.

*Abuse of Charity.*

According to the findings of the subcommittee on charities of the Congestion of Population Commission at least one in every nine persons resident in New York receives annual assistance from charity. 176 societies furnish food, fuel, clothing, and general relief; there are 92 fresh-air charities, 89 societies for the relief of foreigners, 56 for the care of the sick in their homes, 571 societies for other kinds of home relief, 132 to provide relief for destitute or neglected children, and 69 institutions for the defective adults. The object of charity winds up in the hands of one of 12 burial societies. All these societies work apart from some 600 churches, which have their own charitable organisations, and none of the numerous hospitals are included in the foregoing list. Most of these societies have property exempt from taxation and distribute their funds without control by the State, the latter confining its inspections to the few State subsidised organisations. Some 500,000 persons—i.e., as already stated, about one resident in nine—enjoy annually the ministrations of these sometimes unwise and over-liberal associations. The total amount spent annually, exclusive altogether, be it remembered, of what is disbursed in strictly medical relief, is over £7,000,000.

*Antivivisection Tactics.*

The New York State branch of the Society for the Prevention of Cruelty to Animals is about to urge an investigation by the State authorities into the various institutes for pathological research. The object is to obtain the privilege of free and unannounced entry into the laboratories, obviously for the purpose of getting material for absurd and misleading "literature."

Jan. 24th.

## NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

*A Health Department for South Africa.*

DURING the past month in South Africa the value of proper organisation in the profession has been demonstrated. As indicated in previous communications, for some months past efforts have been made to induce the Government to recognise the importance of public health and the necessity for having a properly equipped health department for South Africa. These efforts, however, did not meet with success, but the agitation was continued, and at length came to a head in Parliament. On Dec. 7th Dr. J. C. McNeillie, member for Boksburg, formally moved in the House of Assembly that the Government be requested to consider the advisability of the appointment of a Minister of the Crown with the portfolio of Public Health. In his speech he reviewed the position of the country from a public health standpoint, detailing at length the circumstances leading up to the agitation which was being carried on by medical men throughout the length and breadth of South Africa. Dr. A. C. Neethling, member for Beaufort West, followed, and stated that as a member of the Government party he concurred in what had been said, but, while he considered that eventually a definite portfolio of Public Health would have to be created, he thought perhaps that the profession was asking for too much at present, and he therefore moved an amendment requesting the Government to consider the advisability of creating a proper health department for South Africa under the direct control of a chief medical officer. A long debate ensued in which most of the medical and several lay members took part. The actions of the Government were somewhat freely criticised from all quarters of the House, and eventually the debate was adjourned until the following week. On the 13th the matter was again raised when the estimates were under discussion, and again there was a further debate. In this the Right Hon. J. X. Merriman, ex-Prime Minister of Cape Colony, took the leading part, and in reply to the Minister for the Interior, who had expressed doubts as to the value of the work done by the late Cape Health Department, he warmly defended this department, emphasising the administrative ability and zeal of Dr. A. J. Gregory, its chief medical officer, who was now, he stated, in the extraordinary position of being subordinate to his former clerks. Eventually the Minister for the Interior stated that he held very strong views that medical men should not take any part in administration, but he was prepared carefully to reconsider the whole matter, and in any case he would promise in due course to establish a department of public health and to appoint a chief medical officer. While declaring that he was convinced that the larger issues of public health should remain under the Union, he thought that it would be necessary to appoint provincial medical officers of health, and possibly to delegate to the provincial councils the dealing with all smaller and local health matters. On this the matter dropped, but the discussion on the adjourned motion was resumed the following evening, when in view of the Minister's promise the night before the amendment proposed by Dr. Neethling was formally agreed to. The department, it is hoped, will be charged with the dealing with, *inter alia*, all infectious and dangerous diseases, port health, vital statistics, leper asylums, mines, and the health of labourers on the mines. It is hoped, also, that it will undertake investigation and research into the numerous diseases peculiar to the country, and administer the bacteriological and chemical laboratories, other than those engaged solely in veterinary or agricultural work. It should control district surgeons. It might also be conveniently charged with all general medical work, such as the administration of the lunacy laws and the Medical Acts. Some anxiety is felt lest a department in name only should be established, with a chief medical officer without any administrative functions whatever, and the profession in South Africa is therefore anxiously awaiting developments.

*The Segregation of Lepers.*

A debate of some importance took place on Dec. 13th on the subject of leprosy, when a motion was moved in the House of Assembly praying for the removal of the Robben Island lepers to the mainland. This question is one which has been constantly brought forward in the late Cape Parliament, and has been the subject of a large number of commissions of inquiry and select committees. These have brought in the most divergent reports, but generally to the effect that the advantages of the island as a leper settlement considerably outweigh its disadvantages. The result has been to lead to chronic unrest amongst the lepers, a condition which has apparently been aggravated by lay administration. Dr. D. B. Hewat, member for Woodstock, stated in connexion with the motion that he had grave doubts whether leprosy, or at any rate anæsthetic leprosy, was contagious or infectious at all, and he pleaded for a commission of experts to go into the whole question afresh. A number of other members took part in the discussion and very divergent opinions were expressed. General Smuts, in reply, stated that the whole question must be sympathetically treated by the Government. The State had to be very careful to segregate lepers in the interests of the general community. He knew that there were matters to complain of at Robben Island. It would be impossible to administer a settlement of this sort without complaints. The Transvaal Leper Asylum, with which he was personally acquainted, was, he considered, one of the best in the world, and yet he had complaints from this asylum. He expressed his conviction that even if the patients from Robben Island were removed to the mainland, that would not stop agitation for release from segregation by the lepers. The line drawn in South Africa was, he considered, a safe one; the matter was very largely left in the hands of their experts. If a case was considered by

their experts suitable for segregation at home, then the patient was permitted under certain conditions to live at home, but, if not, then removal to an asylum was necessary. He thought that discussions on leprosy in the House could only lead to further agitation amongst the lepers, and he therefore deprecated the matter having been brought forward. He thought that the Government should vigorously encourage the prosecution of research on leprosy. The Cape Government had appointed a bacteriologist for leprosy research on the island, and this gentleman was doing good work. The present Government was trying in addition to persuade Dr. G. Turner, formerly medical officer of health of the Transvaal, and one of the greatest experts on leprosy in the world, to return to South Africa. It was, in his opinion, useless having commissions on leprosy, but he quite agreed that they should endeavour to advance their knowledge of the disease by employing trained medical men to undertake research work at existing asylums. With this the debate ended. It is, I think, fully recognised by most medical men that there are drawbacks from a medical point of view to Robben Island as a leper settlement, but these drawbacks are mostly capable of being remedied. Moreover, the leper inhabitants on the island are not confined to small areas, but are able to roam at will over practically its whole extent. Although it has often been represented that Robben Island is unsuitable, and that its leper inhabitants will never be contented until removed to the mainland, it is of interest to note that when the Government of the Orange River Colony in 1908 or 1909 formed a leper settlement in that colony, and arranged for the withdrawal of its lepers from Robben Island, a large number of these lepers are stated to have strongly objected, on the grounds that they were well aware that they enjoyed greater freedom and lived under happier conditions than would be possible if settled inland in their own State.

*Memorial to the late King.*

Her Excellency the Viscountess Gladstone is, it is understood, about to make an appeal to the public in South Africa for funds to establish a national memorial to his late Majesty King Edward VII. A few weeks ago a number of influential people were called to Government House, Cape Town, when, after discussing the proposal, the following resolutions were agreed to:—

1. That this meeting resolves that it is advisable to raise a national South African fund with the object of establishing a memorial to his late Majesty King Edward VII.
2. That a Provisional Committee be formed to consider the question of devoting the fund to the formation of a nursing association or some other scheme for the alleviation of human suffering, as to the estimated scope and requirements of such a project, what funds would appear to be needed for the various schemes, holding in view the permanent nature of the object, and generally to report.

It is believed that Her Excellency's own proposal is likely to be adopted—namely, the establishment of an order of trained nurses on the lines of those which have been instituted in India, Canada, and Australia. The nurses under such a scheme would be allocated to different districts and would be controlled by district committees composed of local representatives under the general supervision of a central committee, the expenses of maintenance being met partly by fees fixed as far as possible within the means of those requiring the attendance of the nurses, and partly from a central fund raised by public subscription. The alternative proposal is the establishment of one or more central sanatoriums for consumptives. There is no doubt of the need for a scheme for supplying district nurses to outlying villages in South Africa. Those of us who have been in practice in the smaller towns and villages up country know of the grave disabilities under which work has often to be done, owing to the lack of trained nursing assistance. In most up-country places medical men do not attend many midwifery cases except among the wealthier classes, and the majority of confinements are attended by coloured midwives, without training and generally of filthy habits. No wonder, therefore, that the amount of puerperal fever in this country is excessive. If the committee can devise a satisfactory scheme for supplying trained nurses and the scheme can be given effect to much good will result, not only directly, but indirectly, owing to the educative influences which would be at work with the advent of trained nurses into ignorant households—a truly national memorial to a great king.

Jan. 2nd.

# NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

*The Treatment of Snake-bite.*

IN July, 1909, the Madras Government requested the surgeon-general in charge of the Civil Medical Department of the presidency to submit proposals for bringing into more general use among the public the treatment of snake-bite with Sir Lauder Brunton's lancets and permanganate of potash. In October of the same year the Madras Government approved the surgeon-general's proposal to obtain 12,000 lancets for distribution among its subordinates and others in the presidency. The Hon. Surgeon-General P. H. Benson, I.M.S., in his first annual report on the subject, recently issued, describes 15 cases of snake-bite thus treated. He states no definite opinion can be formed as to the efficacy of the treatment until the total number of cases treated with the lancets is fairly large. The Government, in a covering memorandum on the report, considers that the information supplied regarding these cases is so incomplete as to make any deductions from it impossible. It is evident that if any useful information is to be obtained from the experiment further instructions are necessary. It is essential to any useful conclusion that the identity of the snake by which the bite was inflicted shall be authoritatively determined. Directions have accordingly been issued as to sending the snakes killed for identification to the superintendent of the Madras Museum.

*A New Hospital for Aundh State.*

The need of good hospitals is nowhere more felt than in the native States which are dependent on their own revenues for the erection and maintenance of dispensaries and such-like institutions. In the Aundh State there are at the present time only three dispensaries, situated at long distances from one another, and this fact has been early recognised by the present occupant of the *gadi*, Shrimant Bala Saheb, Pant Prathinian, who shortly after his installation, towards the close of 1909, sanctioned an estimate for the building of a hospital in the capital city, Aundh. At his invitation several European and native gentlemen recently witnessed the ceremony of laying the foundation-stone. A small camp has been laid out by Mr. Jussuff H. Jaffer of Poona, and the comfort of the guests during their brief stay was well looked after by him, and the State Karbhari, Khan Bahadur Jacob Bapuji. The ceremony of laying the foundation-stone of the institution was performed by Mr. Bonus, I.C.S., Collector of Satara and Political Agent of the Aundh State, before a large gathering assembled in a decorated *shamiana* on the building site, and before a large gathering of native officials and gentlemen of the State. The site selected is an elevated piece of ground (about four acres in extent) in the township of Aundh, and the building when completed is estimated to cost close on Rs. 40,000. It will be a stone structure 150 feet in length by 30 feet in breadth, of a single storey, and will be in charge of an Indian medical man, and is to be called "The King-Emperor Edward the Seventh Hospital."

*Sanitation in Kashmir.*

The cholera epidemic, which appeared in Srinagar and thence spread to other parts of Kashmir last summer, has again drawn attention to the insanitary condition of that otherwise charming country. Municipal scavengers under proper supervision would work wonders for the sanitation of Srinagar. The provision of a good supply of potable water would involve considerable expenditure, but improvement in the health of Srinagar largely depends on there being every year some extension of a water-pipe connexion into areas where at present the people depend for their drinking-supplies on all sorts of contaminated sources. Long years of misery and poverty have made the people lazy and indifferent, ready to follow blindly the insanitary practices of their fathers, but every additional hydrant helps to wean a certain number from their ancient customs and leads them to value the provision of a pure water-supply. As the City of London was freed from the visitations of plague by the Great Fire, which swept away thousands of crowded tenements and insanitary areas, so it is probable a great conflagration might not be an unmixed evil in many an eastern town. But

without such a drastic remedy in Srinagar there is much that can be done in the way of immediate improvement. To carry out all the obvious reforms nothing more is required than common-sense, energy, perseverance, and a sufficient supply of money. Expenditure under proper sanitary supervision would speedily repay itself. An epidemic such as that of last summer does more than merely carry off a thousand or so of valuable lives, it dislocates State administration, paralyses trade, and frightens away visitors, thereby depriving the State of the very large sums annually spent in the country. For this reason the improvement of sanitation in the capital town of the State of Kashmir is a work which should commend itself to the authorities as urgently necessary and economically sound. The appointment of a suitably qualified medical officer of health such as is being done in the larger towns in India might well repay the State.

*The Prevention of Malarial Fevers.*

The Lieutenant-Governor of Bengal has appointed a Provincial Malaria Committee composed as follows: President, the Executive Member of Council in the Municipal (Medical) Department, the two secretaries in the Public Works Department, Major Leonard Rogers, I.M.S., Assistant Surgeon U. N. Bramachari (Teacher of Medicine, Campbell Medical School), Dr. Nil Ratan Sircar, and the Sanitary Commissioner of Bengal (secretary). It is hoped that by the appointment of this committee the inquiries regarding malaria will be conducted on more systematic lines than hitherto has been the case, and a coördination will be secured with the lines of prevention taking place in other parts of India.

Jan. 12th.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

*Peculiar Poisoning Case.*

A REMARKABLE case of poisoning has occurred at Prahran, an industrial suburb of Melbourne. A family, consisting of a mother and three daughters, partook of a meal which comprised ham sandwiches, tinned tongue, cucumber, and ice-cream. Shortly afterwards the mother and two of the daughters were taken violently ill. One girl died within 24 hours and the second was removed to the Alfred Hospital, where she also died a few days later. The cases were regarded as ptomaine poisoning, and although a magisterial inquiry was held after the second death the magistrate decided that no necropsy was necessary. A day or two later the mother, who had been under treatment by Dr. C. A. Altmann, also died suddenly after having apparently convalesced. Dr. Altmann refused a certificate and insisted on a necropsy, which was made by Dr. Crawford Mollison, who discovered large quantities of arsenic in the body. The bodies of the two girls were thereupon exhumed, and it is stated that arsenic has also been found in each body. The third sister now stands charged with the murder of her mother, the police having found that this daughter purchased arsenic from a local chemist for the alleged purpose of destroying rats. The case has been adjourned pending the completion of the coroner's inquiry.

*Medical Inspection of Schools.*

The first report of the inspection of Victorian State school children has been issued. Under an outline scheme in the report it is proposed that each child shall be examined four times during its school career, or once in two years. There are 90,000 children in urban areas, and these will be first dealt with. An estimate is made of 34,000 yearly examinations, which will entail six extra inspectors in addition to the three at present acting. It is recommended that they be paid £400 each per annum. Eight part-time officers at £50 each per year are also recommended. The present report deals with about 3000 children. The examiners say: "The marked prevalence of certain defects has been very evident, but no less evident has been the rarity of other well-known defects—for example, tuberculous glands in the neck, trachoma, skin diseases generally, and special deformities such as club-foot, hare-lip, and infantile paralysis. There has been a relatively small number of children giving a history of scarlet fever, diphtheria, or rheumatism." As regards defective vision, 6·8 per cent. are stated to have shown gross defect and 10·5 per cent. slight defect. Hearing showed 8·5 per cent. with gross defect and 10·5 per cent. with slight. Nine per cent. of boys and 6 per cent. of girls showed under-nutrition; 13·5 per cent. of girls but no boys showed over-nutrition.

*Radium.*

The Treasurer of Victoria has obtained from Dr. B. B. Ham, chairman of the Board of Health, a report on radium, and the advisability of making a supply available for medical men. Mr. Watt states the Government will take up any feasible scheme that may be presented for such a purpose.

*Early Closing for Pharmaceutical Chemists.*

An early closing movement for chemists has been mooted in New South Wales, under which it is proposed that only urgent prescriptions shall be dispensed after hours. The proposal has not yet assumed definite shape, but some medical men in club practice consider that their work would also be lightened by an earlier closing of chemists' shops. The usual hour at present is 9 P.M.

*Obituary.*

The death is announced of Dr. Mary Page Stone in very sad circumstances. The late Dr. Stone was visiting a patient on her bicycle and collided with a dray, being thrown violently to the ground. At first her injuries did not appear serious, but she collapsed suddenly and died from internal hæmorrhage about 12 hours after the accident. Dr. Stone was a graduate of the University of Melbourne with a distinguished record, and had a large private practice. She was also a prominent member of various philanthropic and educational movements, particularly as regards the education of women.

Dec. 20th, 1910.

# Obituary.

## FREDERICK MELLAND, M.R.C.S. ENG., L.S.A.

BY the death of Mr. Frederick Melland the medical profession in Manchester has lost its oldest link with the past. He was born at Alport in Derbyshire in 1818, and had nearly completed his ninety-third year at the time of his death on Jan. 17th. He died at his house in Victoria Park, Rusholme, in which neighbourhood he had lived during almost the whole of his active medical life. The old system of apprenticeship was, of course, in existence in his early days, and he began his career as an apprentice in Sheffield, going to Manchester to complete his studies. He passed the examination of the Society of Apothecaries, the "Hall," as it used to be called, in 1840, and the Royal College of Surgeons of England, in 1841. After being for a time one of the resident officers at the Royal Infirmary, he settled down to a long and honourable career of general practice, from which he retired only about ten years ago. He was greatly respected by a wide circle of patients and friends for his genial, kindly disposition and loyalty, and attracted and impressed those with whom he had social or professional relations. His own practice did not, however, absorb all his energies, for he was connected with the Chorlton Dispensary and the Ancoats Hospital for many years. When any man lives to his ninety-third year it is not surprising to hear that he was a man of fine physique and activity. Only a few months ago he went to London to be present at the wedding of his grandson, Mr. Herbert Asquith, the second son of the Prime Minister, for, in 1877, the Prime Minister married Mr. Melland's eldest daughter as his first wife. Mr. Melland was for 46 years district medical officer to what is now known as the South Manchester Union, being appointed in 1850 and retiring in 1896. At their last meeting the guardians passed a vote of regret and condolence with Mr. Melland's family, and the chairman, Mr. Macfarlane, in the course of his remarks, said, "He was a worthy citizen and a man who was held in the highest respect in this city." Mr. Melland's chief recreations were travel and reading, and although a Nonconformist he took a great interest in church architecture. He has left a family of several sons and three daughters. Two of the sons are in the medical profession, one practising in Bowdon and the

other in Manchester. The funeral took place on Jan. 21st at the Manchester Crematorium.

GEORGE BIRT, M.B. LOND., M.R.C.S. ENG., L.S.A.

THE death is announced as occurring at Teignmouth on Jan. 25th of Dr. G. Birt, second son of the late Dr. T. Birt of Leamington, at the age of 64 years. He matriculated at the University of London and entered the Birmingham Medical School, whence he obtained the diplomas of M.R.C.S. and L.S.A. After being resident on the surgical side of the General Hospital, Birmingham, he continued his studies at University College, and graduated in medicine at the University of London, gaining honours in anatomy and organic chemistry. He settled in Stourbridge, and up to the time of his retirement was engaged in a widespread general practice in that district. He held the post of honorary surgeon to the Stourbridge Dispensary. "His strenuous life," writes one who knew him well, "which did not permit of relaxation, recreation, or even an annual holiday, began to imprint its mark in 1903. Glycosuria and signs of arterio-sclerosis made their appearance. With unabated courage he continued work, ignoring all danger signals. At length in 1908 the incessant strain, unrelieved by rest, overcame him. He retired to Teignmouth an invalid. Early in December last cardiac compensation began to fail, hydrothorax developed and required frequent paracentesis. Uræmia closed the scene."

Dr. Birt married in 1877 the daughter of the late Dr. Campbell of Stourbridge, by whom he is survived. He leaves a son and two daughters.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Willibald A. Nagel, professor of physiology in the University of Rostock, after a long illness. He published numerous researches and papers dealing especially with the physiology of the mind. His age was 40.—Dr. Johann Csocor of Mödling, professor in the veterinary school and *docent* in the Vienna University Medical Faculty, aged 67.—Dr. Willis Goss Macdonald, professor of surgery in Albany Medical College.—Dr. Lesouef, formerly Member of the French Senate.—Dr. Hocquart, inspecting medical officer of the French army.—Dr. Alban de la Garde, formerly professor of pathology in the Poitiers Medical School.

# Medical News.

UNIVERSITY OF LIVERPOOL.—At the examination for the Diploma in Public Health held recently the following candidates were successful:—

J. Green, S. M. Green, Blanche M. Z. Johnston, W. W. Mackarell, S. P. Mort, and J. F. Whelan.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Adolf Gutmann has been recognised as *privat-docent* of Ophthalmology and Dr. Hermann Beyer as *privat-docent* of Otology.—*Bologna:* Dr. A. Codivilla has been appointed Extraordinary Professor of Orthopædic Surgery.—*Buenos Aires:* Dr. Ricardo S. Gómez has been appointed to the chair of Descriptive Anatomy and Dr. Daniel J. Cranwell to that of External Pathology.—*Cagliari:* Dr. Giovanni Mandri has been recognised as *privat-docent* of Medicine.—*Heidelberg:* Dr. Moro of Munich has been offered the position of Extraordinary Professor of Children's Diseases and Director of the University Children's Clinic, in succession to Dr. Feer.—*Marburg:* Dr. M. Matthes, Director of the Academical Clinical Institutions in Cologne, has been appointed Professor of Medicine and Director of the Medical Clinic and Polyclinic, in succession to Professor Brauer, who is going to Hamburg.—*Rostock:* Dr. Karl Walter has been recognised as *privat docent* of Anatomy.—*Vienna:* Dr. Lothar v. Frankl Hochwart has been appointed Extraordinary Professor of Neurology, and Dr. Karl Landsteiner, Extraordinary Professor of Pathological Anatomy. The title of Professor has been granted to Dr. Rudolf Frank, *privat-docent* of Surgery; Dr. Alois Strasser, *privat-docent* of Hydrotherapy; Dr. Hans Koschier, *privat-docent* of Laryngology; Dr. Gustav Singer, *privat-docent* of Medicine; Dr. Josef Adolf Hirschl, *privat-docent* of Psychiatry; Dr. Ludwig Braun, *privat-docent* of Medicine; Dr. Karl Biehl, *privat-docent* of Otology; Dr. Wilhelm Lalzko, *privat-docent* of Gynæcology; Dr. Emil Raimann, *privat-docent* of Psychiatry; Dr. Julius Schottländer, *privat-docent* of Gynæcology; and Dr. Ernst Pick, Adjunct in the Institute of Serotherapy.

SLEEPING SICKNESS IN RHODESIA.—We understand that a special commission will be appointed by the British South Africa Company to investigate the share taken by the Glossina palpalis and morsitans in the transmission of sleeping sickness in Rhodesia. The commission, it is stated, will consist of Dr. Aylmer W. May of Northern Rhodesia, Dr. A. Kinghorn of Liverpool, Mr. H. Leach of Northern Rhodesia, Mr. O. Silverlock, entomologist, and Mr. Jollyman, bacteriologist.

FORTIETH CONGRESS OF THE GERMAN SURGICAL SOCIETY.—This Congress will take place from April 19th to 22nd, 1911, in Berlin (Langenbeckhaus, Ziegelstrasse, 10 and 11). The proceedings commence on April 19th at 10 A.M., with a celebration of the centenary of B. R. K. Langenbeck's birth. Sessions during the Congress will be held from 9.30 A.M. to 12.30 P.M., and from 2 to 4 P.M. The chief papers to be presented are the following: Free Transplantations, by Herr Lexer; The Disinfection of the Hands and of the Site of Operation, by Herr Küttner; Basedow's Disease, by Herr Kocher; and Cæcum Mobile, by Herr Wilms. These will be followed by papers upon Intravenous Narcosis, Duodenal Ulcer, and the Treatment of Varicose Veins. Dr. L. Rehn, Zimmerweg, 16, Frankfort a.M., is the President. Tickets of membership can be obtained up to April 10th from Herr Melzer, Ziegelstrasse, 10 and 11, Berlin, N. 24.

ARRANGEMENTS FOR CASES OF MEASLES BY THE SOUTHWARK GUARDIANS.—At the meeting of the Southwark board of guardians held on Jan. 12th a report was considered from Dr. H. W. Bruce, the medical superintendent at the infirmary, with reference to the transference of children suffering from measles to one of the fever hospitals of the Metropolitan Asylums Board. Dr. Bruce was strongly of the opinion that the transference of cases of measles, especially in winter, was fraught with great risk to the children, and it appeared to him that if all cases of measles were transferred to a fever hospital a considerable and unnecessary sacrifice of children's lives would be brought about. The children's committee reported that the proposal of the Metropolitan Asylums Board to receive children from the infirmary suffering from measles would not afford any reasonable possibility of reducing the congestion at the infirmary, owing to the fact that a medical certificate of three weeks' observation would be required, and in view of the medical superintendent's statements the committee urged that the Metropolitan Asylums Board be asked to use their vacant accommodation for children suffering from ophthalmia. Mr. T. Cornell said that the proposals of the Asylums Board were misunderstood. They did not propose that cases of measles should be first taken to the infirmary and then transferred to hospital. What was intended, and what was already being carried out in many parts of London, was that the poor cases of measles, for which an admission order to the infirmary had hitherto been given, should be removed direct from their homes to the nearest hospital of the Board, and that no medical certificate of three weeks' observation would be required. The present proposals were first put forward by the Local Government Board. They had been carefully considered by the Asylums Board in the light of experience throughout the country, including that of Edinburgh, Glasgow, and Liverpool, where permanent isolation accommodation was provided in infectious hospitals for cases of measles, and where it had been proved beyond question that measles could be safely treated in the same hospital as other infectious fevers. The Asylums Board had made the provision and it was being generally utilised. It was for the Southwark guardians to say whether they would take advantage of the opportunities offered for the benefit of children for whom they were responsible. The suggestion that children otherwise healthy who were suffering from ophthalmia should be taken into fever hospitals was quite impracticable. After

hearing Mr. Cornell's explanation, the board decided to send cases of measles to the institutions of the Metropolitan Asylums Board.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The Charter Day dinner will take place on Saturday, Feb. 11th. His Excellency the Lord Lieutenant has graciously accepted the invitation of the President and Fellows to be present at the dinner.

A PLYMOUTH CENTENARIAN.—Mrs. A. Moore of Plymouth celebrated the anniversary of her 100th birthday on Jan. 19th. She was born near Bodmin, Cornwall, but has resided in Plymouth for the past 60 years.

LITERARY INTELLIGENCE.—Messrs. Rebman, Limited, will publish this month in Great Britain Major Paul P. Straub's "Medical Service in Campaign," which was reviewed by us in our issue of Jan. 7th. The price will be 6*s*. 6*d*. net.

Dr. W. T. Grenfell, C.M.G., Superintendent of the Royal National Mission to Deep Sea Fishermen, will deliver a public lecture in Queen's Hall, London, on Monday, Feb. 6th, at 8.30 P.M., entitled "Midst Ice and Snow in Labrador" (illustrated with lantern slides). The chair will be occupied by Sir Ernest Shackleton, C.V.O.

THE CARNEGIE HERO FUND.—Mr. Nelson Johnstone, L.R.C.P. & S. Edin., L.F.P.S. Glasg., who rendered assistance to Detective-Sergeant Leeson under a shower of bullets from the alien criminals who established themselves at the house in Sydney-street, Stepney, recently, has received a medallion and £25 from the trustees of the Carnegie Hero Fund.

THE METROPOLITAN HOSPITAL SUNDAY FUND.—At a meeting of the Metropolitan Hospital Sunday Fund, which was held under the presidency of the Lord Mayor at the Mansion House on Jan. 25th, the Rev. Prebendary Anderson was appointed a member of the distribution committee in place of the late Lord Stamford. The members of the general purposes committee and the finance committee were reappointed.

Dr. J. B. Yeoman, medical officer of the Wirral (Cheshire) union workhouse and of Heswall Sanatorium, has been appointed medical officer of health to the Wirral rural district council and six neighbouring urban district councils combining with it, at a salary of £500 a year for five years. The appointment is, of course, subject to the approval of the Local Government Board. The various district councils agree to contribute towards the medical officer's salary in proportion to their present rate assessments, the Wirral rural district council paying £179, the Hoylake and West Kirby urban district council £124, and the other urban district councils £83, £43, £29, £27, and £15 respectively. Dr. Yeoman is allowed to retain the workhouse and sanatorium appointments, but is required to give up his private practice and the union district and vaccination appointments which he holds, and to agree to accept no other public appointments without the consent of the combined councils.

ACTION FOR ALLEGED MEDICAL NEGLIGENCE.—In the Bow county court on Jan. 20th, before Judge Smyly, James John Darkins, a clerk, of Milton-avenue, East Ham, sued Mr. H. de B. Nelson, of Canning Town, for negligence. Mr. Medcalfe appeared for the plaintiff, and Mr. Matthew (on behalf of the London and Counties Medical Protection Society) for the defendant. Mr. Medcalfe said that the case was a serious one, involving the character and reputation of a medical man, but there was no desire on the part of the plaintiff to obtain damages for himself. He simply wanted the recoupment of extra expenses, amounting to between £40 and £50, caused, it was alleged, by the negligence of the defendant. During her confinement in March last the plaintiff's wife was attended by Mr. Nelson, and it was alleged that he left behind pieces of the placenta. After several attacks of hæmorrhage an operation was performed by another practitioner; septic poisoning set in and she died early in May. The allegation was that the defendant was negligent in his attendance and also in his treatment, consequent on which the plaintiff was involved in extra expense in engaging medical men and nurses. The plaintiff gave evidence in support of his counsel's statement. His honour, in summing up, directed the attention of the jury to a letter written by the plaintiff after his wife's death, in which he appealed to the generosity of the defendant to enable him to meet the debts which had been incurred in consequence of the illness. They had to say whether that was a letter which one man would write to another whom he believed to have been the cause of his wife's death. The jury returned a verdict for the defendant. Judgment was given accordingly, with costs.

## BOOKS, ETC., RECEIVED.

BAILLIÈRE, TINDALL, AND COX, London.

Aids to Pathology. By Harry Campbell, M.D., B.S. Lond., F.R.C.P. Second edition. Price, cloth, 3*s*. 6*d*. net; paper, 3*s*. net.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## THE FOUNDER OF "THE LANCET."

*To the Editor of* THE LANCET.

SIR,—May I add to "Bookworm's" citation one or two references to Mr. Thomas Wakley in out-of-the-way literature?

"Sketches by Boz" are, I surmise, but little read in the present day. Written, as they were, at the very outset of Dickens's literary career, they describe social conditions which have since undergone considerable change and are now chiefly interesting to the antiquarian. One article is entitled "A Parliamentary Sketch, with a few Portraits." Of these clever little portraits—word-portraits, of course—five are those of Members of the House of Commons. Thanks to a former owner of my old copy of the "Sketches" (with its capital Cruikshanks), who has thoughtfully supplied in now very faded pencillings the names of the first two upon leaf margins, I am able to identify four of these gentlemen—Colonel C. D. W. Sibthorp, Mr. Thomas Duncombe, Mr. Thomas Wakley, and Mr. John Gully; the identity of the fifth I should like very much to fix. "Boz" points Mr. Wakley out to his readers in these words: "..... the large man in the cloak with the white lining—not the man by the pillar; the other with the light hair hanging over his coat collar behind." If I mistake not, Dickens lived at that time (about 1836) in the Finsbury constituency. (Mr. Gully, it may be stated parenthetically, had been in early manhood, if not an all-victorious, a very successful, votary of the prize ring, afterwards flourishing into a wealthy coal-owner, and Member of Parliament.)

In another book, which is quite rarely met with in the present day, a three-volume work entitled "The Mountain Decameron," written by a medical man (Mr. Joseph Downes) and published in 1836, and highly favourably reviewed, moreover, in the *Quarterly* of the day, the author (vol. iii., p. 275) ridicules the "devoted gallantry" of those Reformers who "value not their heart's blood 'three skips of a louse'" when the "glorious cause of Freedom" is in question. He says: "How! *blood?* Shed your pure blood? Dear, noble gentlemen, do let Mr. Wakley take it, more quietly—with his Lancet, and *be sure*, from the *head*. ..... Your blood, gentlemen, is not exactly the thing wanted by your country, but your good sense and the obedience of a free subject, and its example to the multitude."

There are again allusions to Mr. Wakley in an old book which I have of cuttings, chiefly of leading articles, from the London daily papers of 1829, 1830, and 1831, which clearly indicate that even at this early stage of his eventful career, and when medical reform was levying so heavy a toll upon his time and energies, he yet was in the van in the political struggles of the time. A noticeable thing about these references is that though they occur in cuttings from anti-Reform papers they are consistently marked by a respectfulness that is always denied the other Reform leaders. For instance, "Wakley" is never met with, but "Mr. Wakley." In one place are mentioned "the consistent revolutionists under the guidance of Mr. Wakley"; in another, "Mr. Wakley absolutely governed the meeting," turning the tables, it is explained, upon the "desperadoes"; while farther on he is styled "the Editor of the *Ballot*." In an alarmist 16-page political pamphlet, too, of the same period, entitled "Householders in Danger from the Populace" it is explained that "it is proper to acquit Mr. Wakley, who was to have presided at the meeting [in White-Conduit fields] of connexion with the desperadoes, even to the extent of being totally unacquainted with their projects."

With regard to Mr. Wakley as an orator, Mr. G. H. Francis says in his "Orators of the Age" (1847), at p. 318: "Some of his 'points' have from time to time told remarkably well; such, for instance, as that in which he described the Whig Ministry as being made of 'squeezable' materials. That one expression contributed considerably towards gaining for him the position he holds in the estimation of the House of Commons." I give this quotation for the purpose of asking whether this very expressive term, which is often used in the present day, originated with Wakley. Francis speaks as if it did, and he was just the one who ought to know. Yours faithfully,

Stoke Newington, N., Jan. 16th, 1911. WM. ROBERTS.

## TUNGSTEN IN COURT.

IT is a sign of the times surely when comparatively unheard-of metals become the subject of litigation. Not very many years ago there seemed to be only a limited field of application for tungsten, but now the curiously heavy metal has given rise to an industry of the utmost importance. Carbon has been replaced by tungsten in the filament of the incandescent electric lamp with enormous economic advantages. The conclusion of the recent tungsten lamp patent case promises to place the supply of metallic filament lamps on a more satisfactory basis to both the manufacturer and to the consumer of current for lighting purposes. It appears that the patents of the Osram Lamp Company, the interests of which are controlled in this country

by the General Electric Company, Limited, had been the subject of infringement by Messrs. Boddy and Co. of London, who dealt in Philips tungsten lamps, manufactured by the Philips Metallic Glow Lamp Works Company, Limited, in Holland. The action, which threatened to be a very protracted one, fell through suddenly on the defendants, Messrs. Boddy, consenting to an injunction being granted against them with costs. It was subsequently announced that the Philips Company had acquired from the Osram Company a licence on a royalty basis in respect of the patents under dispute. The public incurs now, therefore, no liability of patent litigation by purchasing the metal filament lamps made under licence granted by the Osram Company (The General Electric Company, Limited) from the defendants in the above case. Some technically-minded people may naturally enough express disappointment that the action did not proceed, for in that case some interesting particulars as to how exactly the metallic filament lamp was made would have been revealed.

## FERTILITY.

*To the Editor of* THE LANCET.

SIR,—I should like to know what are the chances and probabilities of fecundity in a woman of 36, who has just been married. How many years longer would she be likely to be fertile?

I am, Sir, yours faithfully,

Jan. 29th, 1911. OBSTETRICS.

*** We have answered the questions in our editorial columns.—ED. L.

## BOVRIL.

ON Thursday, last week, the Bovril Company gave a large number of medical men from the provinces an opportunity of inspecting the various processes concerned in distributing bovril to the public all over the world. The model premises in Old-street are fitted up with a variety of most ingenious machines for bottling bovril under completely sanitary conditions, and particular interest was taken in the packing-case department in which boxes are made and the parts nailed together by machine. During the afternoon a special demonstration was given by means of the kinematograph of the phenomenon of agglutination of the spirochætæ of fowls, the exhibition including also tick fever, sleeping sickness, Vincent's angina, and syphilis. This demonstration was a source of great interest to the visitors. Lunch was provided, at which over 1200 medical men sat down. Subsequently the Earl of Erroll, K.T., addressed the visitors in a brief speech, in which he explained the great care which the company bestowed upon the preparation of bovril. Sir James Crichton-Browne followed, and referred to the recent physiological experiments which had been made by an independent observer, in which it was shown that bovril increased the assimilation of food very considerably.

## A QUEER SYMPTOM.

*To the Editor of* THE LANCET.

SIR,—I shall be glad if any of your readers can help me to treat a troublesome symptom in one of my patients that so far I have been unable to mitigate. A lady, aged 57, complains of a more or less constant "hot, peppery" taste in her mouth and on her tongue. There is no discoverable organic nervous lesion, and her general health is satisfactory. Suggestions as to pathological causation and treatment will be gladly received by,

Yours faithfully,

Jan. 24th, 1911. CAPSICUM.

P.S.—I have been giving her a course of valerian, in the form called bornyval.

**COMMUNICATIONS not noticed in our present issue will receive attention in our next.**

## A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1911:—

Feb. 20th–25th (Cairo).—Fifth International Congress for the Blind.
March 2nd–6th (Berlin).—Thirty-second Balneological Congress.
,, 23rd (Paris).—First Congress of French Medical Journalists.
April 4th–7th (London).—Fourth Annual Nursing and Midwifery Conference and Exhibition.
April 18th–20th (Paris).—Third Congress of Physiotherapy of French speaking Physicians.
,, 18th (Berlin).—Tenth Congress of the German Orthopædic Surgery Society.
,, 19th–22nd (Berlin).—German Surgical Congress. (Fortieth Annual Meeting.)
,, 19th–22nd (Wiesbaden).—Twenty-eighth German Congress of Internal Medicine.
,, 20th–22nd (Groningen).—Thirteenth Nature and Medical Congress.
May 30th (The Hague).—International Congress on Opium.
May (Washington).—Conference on the Protection of Industrial Property. (Question of False Marking of Goods.)
May–October (Dresden).—International Hygiene Exhibition.
May–October (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May–October (?) (London, Shepherd's Bush).—Coronation Exhibition.
June (Paris).—First Congress of the International Medical Association for the Prevention of War.
,, (Los Angeles, Cal.).—American Medical Association.
June 5th–8th (Kolberg, Prussia).—Fifth International Congress of Thalassotherapy.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
July 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.
August 15th–21st (Dublin).—Royal Institute of Public Health.
,, 30th–Sept. 6th (Portsmouth).—British Association.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September (Brussels).—Exhibition of Fractures.
,, (Turin).—International Congress of Pathology.
,, (Genoa).—International Exhibition of Marine Hygiene.
September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.
Sept. 11th–15th (Berlin).—National Congress for the Study and Prevention of Infantile Mortality (*Gouttes de Lait*).
,, 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
,, 18th–23rd (Sydney).—Australasian Medical Congress.
,, 18th–24th (Turin).—Fourth National Congress of Hygiene.
,, 24th–30th (Rome).—International Congress on Tuberculosis.
,, 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.
October (Cologne).—International Congress of Criminal Anthropology.
Oct. 1st–4th (Liége).—Second Congress of Alimentation.
Dec. 4th–9th (Havana, Cuba).—American Public Health Association.
(Date not fixed) (Montreal).—Canadian Medical Association.
(Date not fixed) (Rome).—International Exhibition of Social Hygiene.
(Date uncertain) (Turin).—International Exhibition of Industry and Labour.

In 1912:—
Spring (London).—Second Optical Convention.
July (?) (Cologne).—International Congress of Nurses.
September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
,, Visit of German Medical Men to America.
Nov. 22nd–29th (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.

In 1913:—
(London).—Seventeenth International Congress of Medicine.
(London).—Historical Medical Exhibition. (Organised by Mr. Henry S. Wellcome.)
(Dresden (?)).—International Conference on Cancer.
(Washington).—Congress of American Physicians and Surgeons.
August (Buffalo).—Fourth International Congress of School Hygiene.

In 1914:—
(Vienna).—Third International Congress for Professional Diseases.

In 1915:—
(London).—International Prison Congress.
(London).—Imperial Exhibition (?)

## METEOROLOGICAL READINGS.

*(Taken daily at 8.30 a.m. by Steward's Instruments.)*

THE LANCET Office, Feb. 1st, 1911.

**The following journals, magazines, &c., have been received:**—Clinical Journal, Liverpool Journal of Commerce, The Referee, British Journal of Dermatology, Weekly Bulletin of the St. Louis Medical Society, Bulletin of the Manila Medical Society, Sanitary Record, Local Government Chronicle, St. Mary's Hospital Gazette, Optician, The Mining Journal, Broad Arrow, Army and Navy Gazette, Folia Therapeutica, Bulletin de l'Académie de Médecine, Archivos Españoles de Neurologia, Psiquiatria y Fisioterapia, Illinois State Board of Health Bulletin, La Clinique Infantile, La Presse Médicale Belge, Hospital Assistant (India), Paris Médical, Quinzaine Thérapeutique, Tidsskrift for den Norske Laegeforening,

Annali di Medicina Navale, Nederlandsch Tijdschrift voor Geneeskunde, Bulletins et Mémoires de la Société Médicale des Hôpitaux de Paris, La Belgique Médicale, Annales de Gynécologie, Sleeping Sickness Bureau Bulletin, Gazzetta Degli Ospedali, Gazette Hebdomadaire des Sciences Médicales de Bordeaux, Guy's Hospital Gazette, The Therapist, Pioneer Mail, Indian Engineering, Medicinische Blatter, The Engineer, Surrey Advertiser, Morning News, Jersey, The Grocer, Literary Digest, Bio-Chemical Journal, Revue d'Hygiène, Peru To-day, Bulletin of the Johns Hopkins Hospital, Monthly Cyclopædia of Medicine, Medical Review of Reviews, Annali dell Istituto Maragliano, Official Gazette of the United States Patent Office, Journal of Meat and Milk Hygiene, Gazette des Sciences Médicales de Bordeaux, Gazette Médicale de Paris, Annales des Maladies des Organes Génito-Urinaires, Times of India, Allgemeine Medizinische Central-Zeitung, British Journal of Dermatology, The Mining Journal, The Journal of Obstetrics and Gynæcology, Critic and Guide, Annales de l'Institut Pasteur, La Presse Médicale Belge, The Transvaal Medical Journal, The Military Surgeon, Tommasi, Presse Médicale d'Égypte, Bulletin de la Société de l'Internal des Hôpitaux de Paris, Cornhill Magazine, Journal of Pathology, The Contemporary Review.

# Medical Diary for the ensuing Week.

## SOCIETIES.

**ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).**

TUESDAY.

PATHOLOGICAL SECTION (Hon. Secretaries—C. Bolton, J. C. G. Ledingham), at National Hospital, Queen-square, W.C.: at 8.30 P.M.

*Laboratory Meeting:*

Dr. C. M. H. Howell: (1) Changes in the Central Nervous System Probably Resulting from the Administration of "606"; (2) The Pathology of Paraplegia in Spinal Caries; (3) Examination of the Central Nervous System in a Case of Syphilis in a Girl aged 21 Years.

Dr. F. W. Mott, F.R.S.: The Changes in the Nervous System in Amaurotic Idiocy.

And other Papers.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries: Albert Carless, James Galloway): at 8 P.M.

*Cases:*

Dr. H. Fletcher Morley: Infantilism with Genu Valgum and Chronic Nephritis.

Dr. H. D. Rolleston and Dr. C. H. S. Taylor: A Result of "Late Rickets."

And other Cases.

**MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.**

MONDAY.—9 P.M., Lettsomian Lecture:—Mr. W. F. Haslam: A Review of the Operations for Stone in the Male Bladder. (Lecture I.)

**HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.**

WEDNESDAY.—8.30 P.M., Dr. J. H. Sequeira: The Progress of Dermatology since Hunter's Time. (Hunterian Oration.)

**UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Grosvenor-road, S.W.**

WEDNESDAY.—5 P.M., Fleet-Surgeon R. C. Munday, R.N.: Beri-Beri, its History in the Navy and in the Persian Gulf.

**PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury-square, W.C.**

TUESDAY.—8 P.M., Prof. W. E. Dixon: The Codex and the Medical Profession.—Mr. W. J. U. Woolcock: The Codex and Pharmacy.

**OPHTHALMOLOGICAL SOCIETY, 11, Chandos-street, Cavendish-square, W.**

THURSDAY.—8 P.M., Card Specimens by Mr. Grimsdale and Mr. Brewerton. Paper: Mr. L. Paton and Dr. G. Holmes: Histopathology of Papilloedema.

**CHILD STUDY SOCIETY, LONDON, 90, Buckingham-Palace-road, S.W.**

THURSDAY.—7.30 P.M., Mr. C. J. Sharp: Recreational Activities: English Folk Dances (with demonstrations).

**HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.**

THURSDAY.—8.30 P.M., Mr. J. Clarke: Two Cases of Abscess of Liver Complicating Appendicitis.—Dr. McCann: The Surgical Treatment of Sterility in Women.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.**

MONDAY AND WEDNESDAY.—5 P.M., Prof. W. d'Esté Emery: The Immunity Reaction in Relation to Surgical Diagnosis.

FRIDAY.—5 P.M., Prof. B. Moore: New Views on the Chemical Composition and Mode of Formation of Renal Calculi, and the Metabolism of Calcium in Gout and Allied Conditions.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.**

MONDAY.—4 P.M., Dr. J. Galloway: Clinique (Skin). 5.15 P.M., Lecture:—Prof. W. Osler: Arterio-Venous Aneurysm.

TUESDAY.—4 P.M., Dr. P. Stewart: Clinique (Medical). 5.15 P.M., Lecture:—Mr. R. H. A. Whitelocke (Oxford): Essentials to Modern Treatment of Fractures.

WEDNESDAY.—4 P.M., Mr. D. C. L. Fitzwilliams: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. L. Mummery: Piles, their Pathology and Treatment (continued).

THURSDAY.—4 P.M., Dr. R. Wells: Clinique (Medical). 5.15 P.M., Lecture:—Dr. W. Carr: Mixed Morbid Conditions in the Chest.

FRIDAY.—4 P.M., Dr. D. Grant: Clinique (Ear, Nose, and Throat).

**POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.**

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Dunn: The Tragedies of Ocular Disease.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. S. Taylor: Rheumatism in Childhood.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Dr. Simson: Gynæcological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. G. Stewart: Disseminated Sclerosis (with cases).

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. G. Stewart: Early Cases of General Paralysis.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Pritchard: Practical Medicine.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

**LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.**

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 4.30 P.M., Special Lecture:—Dr. C. Hughes: Anæsthetics.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 3.30 P.M., Special Lecture:—Mr. Cargill: Differential Diagnosis of Common Diseases of the Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4.30 P.M., Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4.30 P.M., Special Lecture:—Dr. C. O. Hawthorne: Diphtheria, its Later Manifestations.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.**

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. E. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).

TUESDAY.—Clinic:—10 A.M., Medical Out-patient (Dr. A. G. Auld). Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 2.30 P.M., Operations. 3.30 P.M., Medical In-patient: (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Dr. A. G. Auld: Fibroid Phthisis.

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Lecture:—Dr. T. R. Whipham: Empyema.

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.**

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. R. Russell: Muscular Atrophy.

FRIDAY.—3.30 P.M., Clinical Lecture:—Mr. D. Armour: Paraplegia and Pott's Disease.

**CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.**

TUESDAY AND FRIDAY.—3.45 P.M., Lecture:—Dr. D. McKenzie: Ear.

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.

TUESDAY.—5.15 P.M., Demonstration:—Mr. O. L. Addison: General Surgical Diseases—Acute and Chronic Inflammatory Lesions of Bone, Syphilis, Tuberculosis, &c. (Special Post-Graduate Course.)

THURSDAY.—4 P.M., Demonstration—Mr. Kellock: Surgical Cases.

FRIDAY.—5.15 P.M., Demonstration:—Mr. O. L. Addison: General Surgical Diseases—Diseases of Bone (continued). Tumours, Fractures, Separation of Epiphyses, Dislocations. (Special Post-Graduate Course.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Fungous Diseases of the Skin.—I., Tinea Circinata; II., Tinea Imbricata; III., Tinea Versicolor; IV., Erythrasma; V., Actinomycosis: VI., Madura Foot.

LONDON HOSPITAL MEDICAL COLLEGE, Clinical Theatre, London Hospital, Mile End-road, E.

TUESDAY.—1 P.M., Clinical Surgery Lecture:—Mr. E. H. Fenwick: A Method for the Accurate Measurements of the Movements of the Human Kidney before Operation, and its Bearing on Renal Surgery.

LANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Mr. W. R. Douglas: Differential Diagnosis of Chronic Neck Swellings. (Post-Graduate Clinic.)

## OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY (6th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

**TUESDAY (7th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

**WEDNESDAY (8th).**—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

**THURSDAY (9th).**—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

**FRIDAY (10th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor. 9 A.M., Major, 2 P.M.).

**SATURDAY (11th).**—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.) Hospitals operations are performed daily.

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1910 were given in THE LANCET of Dec. 31st, 1910.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1910 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 1 0 | One Year ... ... ... | £1 5 0 |
| Six Months ... ... ... | 0 12 6 | Six Months ... ... ... | 0 14 0 |
| Three Months ... ... | 0 6 6 | Three Months ... ... | 0 7 0 |

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

### TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

## Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Amazon Rubber Co., Manchester; Dr. F. J. Allan, Lond.; Dr. T. R. Atkinson, Lond.; Mr. J. Johnston Abraham, Lond.; Dr. S. A. Arany, Lond.; Dr. D. Moore Alexander, Liverpool; After-Care Association, Lond., Secretary of; Dr. S. J. Aarons, Lond.

B.—Mr. F. J. Bishop, Lond.; Messrs. R. and J. Beck, Lond.; Lieutenant-Colonel C. Birt, R.A.M.C., Dublin; Mr. F. A. Brockhaus, Lond.; Mr. T. Bell, Uppingham; Mr. T. Brown, Glasgow; Mr. W. A. Brend, Lond.; Bedford County Hospital, Secretary of; Mr. Haydn Brown, Caterham; Mr. E. Baker, Birmingham.

C.—Mr. F. W. Clarke, Chorlton-cum-Hardy; Mr. B. K. Coomar, Calcutta; Dr. Albert Churchward, Lond.; Dr. John Cabburn, Lond.; Dr. D. J. Connolly, Ashton-on-Mersey; *Clinical Medicine*, Chicago, Editor of; Convalescent Homes Association, Lond., Secretary of; Dr. A. C. Coles, Bournemouth; Capsicum; Mr. R. G. Carey, Peterborough; Messrs. J. and A. Churchill, Lond.; Messrs. E. Cook and Co., Lond., Mr. W. H. Coates, Hucknall Torkard.

D.—Mr. G. B. Dixon, Birmingham; Lieutenant A. H. T. Davis, R.A.M.C. Trimulgherry; Messrs. W. Dawson and Sons, Lond.; Mr. E. Drake, Lond.; Dorland Advertising Agency, Lond.; Mr. John G. Deakin, Swansea; Mr. A. S. Dutton, Oxford; Dr. Georges Deverre, Paris.

E.—Dr. F. W. Edridge-Green, Lond.

F.—Messrs. Harvey Frost and Co., Lond.; Fine Art Society, Lond.; Frame Food Co., Lond.; Messrs. Fairchild Bros. and Foster, Lond.; F. W.

G.—Guest Hospital, Dudley, Secretary of; Ghyllwoods, Cockermouth, Secretary of; Dr. J. W. Geddes, Middlesbrough; Major T. W. Gibbard, R.A.M.C., Lond.; Mr. J. C. Ghosh, Manchester; Dr. J. A. Glover, Lond.; Messrs. Green and Sons, Edinburgh; Glasgow Maternity Hospital, Superintendent of.

H.—Dr. H. W. Hart, Hyères; Mr. A. Haslewood, Buxton; Mr. Evans G. Hughes, Nevin; Dr. Harold A. Haig, Cardiff; Dr. Field Hall, Lond.; Harrogate Corporation Baths, Manager of; Halifax Guardians, Clerk to the; Dr. Eustace Hill, Durham; Mr. J. Hall-Edwards, Birmingham; Messrs. Hesse and Savory, Teddington; Mr. J. Hart, Lond.

I.—Institute of Chemistry, Lond., Registrar and Secretary of.

J.—Mr. John Jackson, Lond.; Dr. J. V. Jha, Ahmedabad; J. C.; Mr. S. J. Jenkins, Henllan; Mr. E. B. Jones, Lond.; Mr. L. A. Johnson, Normanton; Mr. A. C. James, Bristol.

K.—Messrs. R. A. Knight and Co., Lond.; Messrs. H. S. King and Co., Lond.; Dr. Knight, Edinburgh; Mr. E. W. Kidd, Middlesbrough; Messrs. D. J. Keyner and Co., Lond.; Messrs. C. Knight and Co., Lond.; Messrs. Knoll and Co., Lond.; Mr. J. B. C. Kershaw, Liverpool; Mrs. Kayser, Fleet.

L.—Mr. H. K. Lewis, Lond.; London Temperance Hospital, Resident Medical Officer of; Miss R. Lewin, Ilford; Lecture Agency, Lond.; Professor J. N. Langley, Cambridge; Messrs. Luzac and Co., Lond.; Mr. C. L. Leipoldt, Lond.; Major C. Lynch, Washington, U.S.A.

M.—Mr. J. D. Mortimer, Lond.; Medical Society of Liverpool, Secretary of; Medical Sickness and Accident Society, Lond., Secretary of; Medical and Dental Defence Union of Scotland, Glasgow, Secretary of; Dr. A. Louise McIlroy, Edinburgh; Messrs. Macmillan and Co., Lond.; Medical Society and Medical Institute for Women, Kharkov; Manchester Medical Society, Librarian of; Messrs. Munitiz and Co., Liverpool; Mr. W. J. Midelton, Bournemouth; Mr. T. Mohan, Pontyrhyll; Mr. H. C. McBryan, Box; Mr. R. W. McCafferty, Glen Mills, U.S.A.; Dr. J. B. Mawdsley, Oldham; Dr. H. Mignon, Le Vésinet.

N.—Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.; North Staffs Infirmary, Hartshill, Secretary of; *Newcastle Daily Journal*, Manager of.

O.—Mr. Edmund Owen, Lond.; Messrs. Oppenheimer, Sons, and Co., Lond.; Professor W. Osler, Oxford.

P.—Messrs. Peacock and Hadley, Lond.; Messrs. Powell and Co., Lewes; Dr. R. Pelligrini, Venice; Mr. R. H. Aders Plimmer, Lond.; Messrs. Parke, Davis, and Co., Lond.; Dr. F. W. Price, Lond.; Mr. R. W. Prentice, Lond.; Prince of Wales's General Hospital, Lond., Director of.

R.—Mr. O. Rothacker, Berlin; Messrs. Robertson and Scott, Edinburgh; Radcliffe Infirmary, Oxford, Secretary of; Ransom Sanatorium, Sherwood Forest, Secretary of; Major J. C. Robertson, I.M.S., Lucknow; Dr. W. Roxburgh, Troon; Mr. Harry M. Roberts, Stevenston; Mr. John Ritchie, jun., Boston; Dr. John J. Robertson, Portpatrick; Dr. Charles Ruata, Perugia; Royal Victoria Infirmary, Newcastle-upon-Tyne, Secretary of; Mr. Bernard Roth, Lond.; Research Defence Society, Lond.; Registrar-General for Scotland, Edinburgh; Mr. W. H. D. Rouse, Cambridge; Mr. W. Ramsay, Melbourne; Royal Hampshire County Hospital, Winchester, Secretary of.

S.—Mr. Frederick Spicer, Lond.; Messrs. Stewardson and Co., Fakenham; Mr. G. H. Savage, Lond.; Dr. Edmund M. Smith, York; Dr. J. E. Squire, Lond.; Strand Chemical Co., Lond.; Mr. R. Schoetz, Berlin; Southampton Free Eye Hospital, Secretary of; Mr. P. Swanseger, Ngaruawahia, New Zealand; Messrs. Street and Co., Lond.; Dr. R. Sutherland, Moretonhampstead; Messrs. Spiers and Pond, Lond.

T.—Trained Nurses' Annuity Fund, Lond.; Taunton, Town Clerk of; Mr. S. Thornley, Newport, Monmouthshire; Dr. W. H. Maxwell Telling, Leeds; Mr. J. Thin, Edinburgh.

U.—Messrs. Urban and Schwarzenberg, Berlin.

V.—Dr. A. Vost, Glasgow.

W.—Mr. H. Ewan Waller, Birmingham; Dr. Eric A. Wright, Romford; Dr. I. Walker-Hall, Bristol; Dr. G. A. Wright, Bowdon; Mr. W. Watson, Hull; Mr. W. H. Whiteway-Wilkinson, Teignmouth; Messrs. Widenmann, Broicher and Co., Lond.; West London Medico-Chirurgical Society, President and Council of; W. P.; Dr. O. R. M. Wood, Woolpit; Dr. J. W. Watterson, Morecambe; Dr. C. L. Wheeler, Brooklyn.

Y.—Dr. E. H. Young, Okehampton.

Z.—Messrs. C. Zimmermann and Co., Lond.

## Letters, each with enclosure, are also acknowledged from—

A.—Dr. J. A. Armitage, Wolverhampton; Apollinaris Co., Lond.; Ardath Tobacco Co., Lond.; A. G.; A. J. D.; Army and Navy Male Nurses' Co-operation, Lond.; Messrs. C. Ash, Sons, and Co., Lond.; A. P.; A. L.; A. S.

B.—Dr. J. Barnicot, Hitchin; Messrs. S. H. Benson, Lond.; Mr. W. G. Burcombe, Lincoln; Mr. C. S. Brewer, Birkenhead; Mr. H. Brice, Exeter; Berkshire Education Committee, Reading, Secretary of; Messrs. Black, Geoghegan and Till, Lond.; Mr. H. R. H. Bigg, Lond.; Messrs. T. B. Browne and Co., Lond.; Dr. J. C. Bowie, Tresta; Barnwood House Hospital, Gloucester, Medical Superintendent of; Mr. J. J. Barry, Fermoy; Bradford Children's Hospital, Secretary of; Dr. T. W. Beazeley, Birmingham; Lieutenant-Colonel C. Birt, R.A.M.C., Dublin.

C.—Mr. F. R. Cave, Torquay; Messrs. E. W. Carling and Co., Lond.; C. W.; Cheltenham Eye Hospital, Secretary of; Cardiff Infirmary, Secretary of; Dr. G. L. Cox, Birkenhead; Messrs. Curling, Wyman, and Co., Lond.; Dr. J. Cooke, Lincoln, New Zealand; Dr. T. H. Conarroe, Philadelphia, U.S.A.; Mr. E. Collins, Sawbridgeworth; C. A. A. D.; Messrs. A. H. Cox and Co., Brighton; Cheltenham General Hospital, Secretary of; County of Lanark, Hamilton, Treasurer of Middle Ward.

Warden, Paris; Wonford House Hospital, Exeter; Wolverhampton General Hospital, Secretary of; Wye House, Buxton, Medical Superintendent of; West London Hospital Post-Graduate College, Dean of; Dr. E. Walford, Cardiff; W. H. P.; Mrs. P. Wood, Crawley; Dr. T. Wholey, Pevensey; Mr. H. Wickham, Rufford; Mr. W. Watkins, Llangattock; Dr. J. Wotherspoon, Lond.; Warneford Hospital Leamington, Secretary of; Mr. H. de C. Woodcock, Leeds; Warneford Asylum, Oxford, Secretary of.

Y.—Mr. J. H. olland, Bromley.

# An Address

ON

# THE CLINICAL ASPECTS OF EMOTION AND ACTION.

*Delivered to the Members of the North London Medico-Chirurgical Society, at the Great Northern Hospital, Holloway-road, London, N., on Jan. 12th, 1911.*

BY THOMAS CLAYE SHAW, M.D. LOND., F.R.C.P. LOND.,

EMERITUS LECTURER ON PSYCHOLOGICAL MEDICINE, ST. BARTHOLOMEW'S HOSPITAL, LONDON.

MR. CHAIRMAN AND GENTLEMEN,—In accepting the honour of an invitation by the council of this society, forwarded to me by the chairman, to address you on some subject chosen by myself, I have concluded that as physicians and surgeons meet on the common platform of disorders of the nervous system, I might profitably occupy your attention by speaking about a puzzling class of cases which come early under notice in general practice, and ultimately are often referred to the specialist—cases which are not only of great importance to the individual, but which radiate into the nooks and crannies of social and domestic life, and perhaps at last issue in legal complications. And the worst is that the arbiter before which these cases finally come for adjudication is itself in a parlous state, incomplete and out of date. The law which is supposed to deal with the conditions of life and property is rarely in the same parallel with things as they are. Perhaps it is not its duty to anticipate—it cannot apparently keep even pace with modern developments, and as it lags behind it often deals unfairly with scientific truth. Nowhere is this more conspicuous than in dealing with affections of mind.

It is allowably true that we do not now know much more than our ancestors about the real nature of mind, though we certainly do know much more about the *disorders* of mind, and of the true significance of certain symptoms; but the law retains its canons of responsibility, and, strive as we may, it refuses to be convinced of mental alienation unless in certain directions, even though clinical experience points out the defects in the system of forming judgments.

Fortunately, in one class at least of legal cases judgment is in the hands of men who have some degree of medical training, men who are constantly brought into association with doctors and who can pass beyond the narrow confines on which legal opinions in lunacy matters are based as a rule, and who can see that such factors as Conduct and Emotion may be the indices of unsoundness of mind by *themselves*, and without the accessories which make the insanity of a person manifest to even the man in the street. These men by their practical knowledge have done much to prevent unnecessary law-suits and failures of justice. You must in practice be often brought face to face with cases where things go wrong in the family, where you feel sure that the conduct of one or other of the parties is giving much trouble, and yet where the plausibility of the protagonist in the difficulties and his, or her, general intelligence and conduct in other matters are such that you deem it hopeless, and indeed impossible, to prove legally that a real mental disturbance is at the root of the trouble. There is apparently nothing wrong with what is called the Intellect, the ordinary relations with friends are kept up, strangers see nothing different from usual, and yet a formerly peaceful home is made a hell through a change in one element of a mental content—namely, an alteration in Feeling or Emotion. Or a patient may be observed to be doing things which tend to compromise himself and to imperil his family prospects—all the while that he talks like an angel, professes the best of motives, and shows to the world around him no sign of impairment of intellect which entitles his friends to the protection of the law, and so he is allowed to pursue his career because those responsible for him are afraid of the legal consequences of trying to stop him.

These two conditions, change of Feeling and peculiarity in Conduct, are those which I wish to dwell upon this evening, because their importance as real tokens of mental alienation is not sufficiently recognised, because they are quite as, if not more, connotative of disordered mind as may be the presence of delusions and hallucinations, and because the stoppage of the danger caused by these two factors demands all your courage and tests your strength in the integrity of your knowledge.

## EMOTION AND FEELING.

Just consider for a moment how much Emotion or Feeling enters into the whole domain of animal life. In its lower form of Pain it is the safeguard of existence. Without Pain we should be reckless; without Pleasure we should become indifferent; without Pain life would be very precarious; without Pleasure life would be monotonous and unendurable. And the same is true of the higher emotions. As long as there is Hope we cannot be resigned to destruction, but in the face of the inevitable we accept the situation and submit to it as gracefully as we can. Life, indeed, would scarcely be continuous if it were not for Emotion and Feeling. If it were not for Love and Feeling the continuity of the species would cease, for Duty (which is not strictly speaking an emotion) would certainly not ensure it. Duty does, indeed, *oppose* the continuity of the species except under artificial conditions, backed up by the law.

Now, one thing to notice especially is the *stability* of Emotion and Feeling. Once given they proceed through the life of the individual without change, without radical change, that is, though they may have cycles of intensity. The amorous man retains his *proprium* as long as his potentiality lasts, and even after that has gone the feeling may exist in the form of desires, though if it does not it may simply die away without changing into anything except *indifference*, which is the death of the emotional state. The person who hates a thing will, as a rule, hold his hate to his dying day. He may, of course, dissemble his love or his hate for reasons of diplomacy or policy, but he is never thoroughly attuned to the new rôle, and generally he plays the part badly, rejoicing greatly when he can, as the common saying goes, resume his natural complexion. What is the radical cause of a person's emotional complexion we do not know; whether he is to be of the stamp of "the moody Dane" or of the "gay Lothario" we cannot determine; it is not a case of wealth nor even a case of health always, for the rich man may be a misanthrope and the cripple a philanthropist, but neither the success of the one nor the misfortune of the other can upset the natural bent—like politics, the conservative or the radical trend is constitutional.

On the stability of Emotion, then, we build our social fabric; we shape our ends as regards individuals on the basis that their sentiments and emotional tone are the same as they ever were—not their Ideas, remember, but the emotional tone of their ideas. The benevolent man is the prey of the harpy and the extortioner; the miser is left to his niggardliness, despised and ridiculed. If the man of hitherto fixed mental trend surprises his friends by appearing in a new character, if from being a lively Autolycus he becomes a cross-gartered Malvolio, the first question asked is as to his sanity, and herein lies a great truth, and one that we ought always to keep in front of ourselves—viz., the fact that change in the emotional tones is not the precursor merely of mental instability, but it is a sign that the mischief is actually there—that disease has already begun.

You may ask how it is that if Feeling and Emotion are so stable there has grown up such a saying as "he grew to like it." It is true, especially as regards mere sensation, that a substance which is objectionable at first may become indifferent or even taken without murmur at last, but this is probably due to the influence of a new idea that it is doing good, which finally becomes so strong that it overwhelms the unpleasant tone of the old idea by the substitution of a more agreeable one; but though the old feeling may be overwhelmed it is not extinguished, it is but subordinated to the idea of good which is accruing. So that here, as in very many other things, public assertions are unreliable when analysed.

In the higher region of true Emotion and Feeling it is to be noticed that tendencies, dispositions, may be obscured for a time by the necessities of the moment, but it is only a temporary eclipse, and the obscuration has not changed the real nature of the object. In our daily work as medical men we are very liable to be deceived by appearances, and in no department of medical science is this liability more easy than on the mental side of conditions with which we are

brought in contact—for there is a mental side to every common ailment—so that it is wise to be on the alert and to ask ourselves the question, "Is there here a real change of Feeling or is it only an apparent change, overshadowing for a time and for a purpose the natural trend which is only in hiding and will again coruscate with its habitual intensity?" The difficulty of the situation is that very one which besets us in many of these investigations connected with mental conditions—viz., that we are dependent on the *subjective* assertions of the individual as a guide to what is found in his sayings or doings. If a person says that he has a pain or a headache or a feeling of pressure it is only rarely that we can say that he has not; as a rule we accept the statement and try to find the cause, but there is no real and reliable test for Emotion; we cannot say—except from the actions of the patient—that such and such an emotional tone is really present, and even then we may make a mistake and declare to be benign what is in reality diseased and malignant. When, therefore, I speak of the stability of Emotion I allow that the general trend in one direction may be upset by temporary causes, but the reversion to the real and basic trend soon reasserts itself—the converted poacher will snare a rabbit or net a trout when the temptation occurs, and the regenerate Scrooge will revert to his parsimony when the newness of his benevolence has worn off. Indeed, the protestations of these perverts are frequently too much; they protest loudly to keep up their courage in the new rôle, because they feel that they are just acting a part; it is like putting a coward into a military uniform to make him fight, because the dress may stimulate him into a swashbuckler's bravery, the true quality of which he does not possess.

### CHANGED EMOTIONAL STATES.

As men in practice we often meet with cases where there is a great change of conduct which can only be traced to change in the emotional tone. There are no false ideas about things in general, the patient may remain on the best terms with neighbours, and even at that testing-house of peculiarities, the club, no altruistic change may have been noted, but from your knowledge you will ascertain that in the conduction of intimate relationships there is a radical change in Feeling—and, at first, nothing else. Business conditions may be promoted as usual, but the domesticity of the home is invaded, harmony is interrupted, and where was peace there now reigns discord, impulse becomes the substitute for moderate judgment, and yet nothing can be predicated except a pronounced antithesis in the moods or the emotional accompaniments of the ideas. This change shows itself prominently in feelings toward the husband, for women head the class of this alienation. Love is changed to hate, and, following this, suspicion enters into the field, and then with the presence of unjust and unfounded doubt we are treading closely on the domain of an actually deluded condition. You may take it for granted that at the root of this change there is some sexual trouble.

Freud of Vienna has elaborated his doctrine of "complexes," by which he seeks to cure those cases in which false ideas and changed emotional states are the characteristics of the disorder, by a thorough investigation of the condition of the subconscious mind and its connexions, so as to arrive at the deep-seated influences which, though at first unsuspected, really control ultimate ideas and actions. Freud's process is tedious and complicated; it involves long sessions of examination and argument and perhaps a personal aptitude on the part of the inquisitor, but the process of examination brings out clearly two factors which did not previously receive the attention which they merited—viz., that much of what we feel, say, and do is determined by basic conditions which exist in a subconscious area and are therefore not at once perceived, either by the patient or by the examiner, as being vital to the true conception of the subjective position. It is these deep complexes which must be got at, and it is only after considerable practice and with much application that success can be achieved. Another thing upon which Freud insists, and the importance of it cannot be over-estimated, is the frequent presence of a sexual element in the subconscious area which is of the greatest possible influence as a disturbing factor. I have been much interested in finding how often a sexual element is discovered to be of the greatest importance in the history of a case where it was before examination either unsuspected or ignored. Let us review this sexual element for the purpose of showing how fundamental it is in the life of the individual and as a justification of Freud's theory. The sexual instinct is present very early in the life of the individual—too early one feels inclined to think. It leads the schoolboy into extravagances of conduct which imperil his mental integrity and which probably have an exhausting effect upon his bodily constitution. It may be a necessity—it is, perhaps, none the less a misfortune—that this sexual nisus should come so forcibly into prominence at a time when ignorance is unable to control impulses. However, intercourse is so dependent on the timely development of emotions and sentiments that it may be a necessity for the complete unity of a character, for the proper constitution of mental contents, that the elements of the content shall be nascent and be elaborated together, and that unless this early admixture of ingredients occurred there would arise a mental complex in which charity, benevolence, social amenities, and altruistic considerations would be absent. It may be that an unemotional mental habit, a cold, indifferent, calculating machine, which an intellect without feeling would become, would be detrimental to the career of a world which is manifestly compounded of agreeable and painful experiences. We do, indeed, see from time to time instances of the absence of the gradual rise of sexual promptings, and the result does not commend itself to us as satisfactory; we seem to miss in these people that completeness of sympathy with others, that rotundity of mind and character the want of which banishes these inchoate specimens into a class apart, and ostracises them from the perfected social environment. And the worst of it all is that a process which should be allowed to grow naturally in the quiet harmonious adjustment of reciprocal integrities is fostered, nay, absolutely forced, into premature consciousness. The spectacle of semi-nude and suggestive stage-kickers and poseuses does away with all sense of timely curiosity in the opposite sex. I doubt indeed if it does not seriously damage the matrimonial market. There is little new to look forward to; the young person has at the most critical period of his life been accustomed to the revelations and to the perturbations of a nascent function which should have been sedulously kept in the background and not hothoused by the injudicious fires of those who trade upon the pleasurable side of Emotion and Feeling, careless of the risk to decay brought on by immature functioning. As a consequence, the man either loses early the promptings to marry, or if from social or other considerations he does enter into a matrimonial contract there is apt to be trouble in the early future. Over and over again one meets with mental embarrassments and difficulties due in their basis to sexual inadequacy brought on by the injudicious awakening of forces which should have matured in slumber to produce the harvest in the hey-day of life. I doubt if 50 per cent. of the people who are married are really fit for it! The functions have been so anticipated at pleasure that when they become obligatory they are irksome. What other result can be expected than what one meets with? With the cooling of ardency there arises suspicion, the pride of the woman is injured; she thinks that she has lost her charm and that illicit alliances have been formed. Then comes the occupation of separate apartments and the first stage of the final rupture is completed. Almost invariably in the divorce court reports you notice the fact that the married couple desiring to be separated occupy different rooms, and it seems a necessary corollary that this separation must lead to an alteration in mutual confidence.

Please note that so far we have only arrived at suspicion, probably not well founded, but in a way to be understood as possible to the sound mind. There may be no real change of feeling, but the change of after-circumstances has given rise to a train of ideas which menace the unity of the married life. The case is different, however, when the estrangement happens to concern one of neurotic temperament, in whose family there may have been actual insanity and where exists a tendency to a mental instability from causes which but for this trend would have had comparatively little significance. Here we are face to face with a latent morbid sensitiveness fanned into flame by unfounded suspicions of acts never intended, and productive of conditions which are most serious in their results. It is in this class that we note a distinct change of Feeling—Love is turned into Hate, reconciliation becomes impossible, and we are confronted with the spectacle of the home destroyed, the family

divided into a partisanship of the one side or the other, and ourselves perhaps called in to adjust the balance of parties as best we can. In this change of Feeling without adequate cause and in the face of facts which speak to the contrary we should suspect the early development of an insanity which in time will be apparent to all. In its early stages the friends and sympathisers can see nothing wrong, they listen to and receive as adequate the explanation and statements made, possibly with all coherence and with an air of truthfulness, and as they are not primed with all the facts they see no ground for treating the indignation of the self-made victim with doubt or disapproval. They see no insanity even though you may.

It is a curious thing how people generally consider themselves judges of Insanity! Just as they think the sun goes round the world because they see it drop in the west, so do they conclude that the evils are real because the aggrieved one says so! And our difficulties in these cases are very real, because much as we may know that temporary seclusion or residence under skilled supervision is absolutely necessary in the interests of the patient and others we cannot enforce it. We cannot sign a certificate for compulsory detention because the patient is not certifiable in the accepted sense of the word—she would probably be returned in a short time because there is so much lay and so-called "common-sense" interference with the detention and treatment of persons who do not come up to the legal definitions of insanity, that even those who know better are handicapped in their knowledge and the patient refuses to submit to place herself under a separation treatment which she regards as a branding extinction prompted by the desire to get rid of her for self-seeking purposes. A concrete example of what I mean would work out as follows. A married couple have maintained happy relationship for years and have produced a family. In one of these parents there is a history of a decidedly insane progenitor. All goes well until the advent of the climacteric period or the influence of mental strain asserts itself by the production of a change in the emotional tone which leads to bickering and dissatisfaction in the place of contentment and harmony. If the nature of the change is not noticed there ensues a responsive recrimination, relations become strained, and separate sleeping apartments are adopted as a means of escape by the one from the irritating demeanour assumed by the other. This, not unnaturally perhaps, leads to an aggravation of the changed emotional tone, and there follow accusations of unfaithfulness, of cruelty and unkindness, all of which may be absolutely unfounded, though protestations and even proofs to the contrary of the most convincing nature may be to hand.

It may be said that, if the change in emotional tone has gone so far as to set up these unfounded ideas, the case has already become one of pronounced and certifiable insanity, but it must be remembered that it is only later that these ideas, prompted by the change of tone, assert themselves; at the first they are not demonstrably present, though they may have an existence in the subconscious area. To the careful observer there are frequently other symptoms present, though in public they are not apparent, such as abstention from proper food and insomnia, due to suspicion, anxiety, and other associations set up by the changed state. Suppose a person of this group of symptoms were to commit a crime, either to injure herself or to inflict damage on others, there would be no difficulty for anyone acquainted with the facts in giving evidence as to mental incapacity, and without doubt such evidence would be gratefully accepted by the friends of the patient, the very people who up to the time of this criminal behaviour could see nothing wrong and would have strongly condemned proceedings calculated to prevent such a catastrophe as has happened.

### CONNEXION BETWEEN FEELING AND WILL.

It will probably occur to you, and you have the right to ask, if Emotion or Feeling is not a thing by itself but is merely the tone of an idea, does not the very fact of a change in emotional tone connote a change in idea, and *ipso facto* indicate that we are in the presence of a delusion? I think that if you do so contend you are right, and, moreover, that there is present an actual physical basis for your contention, but you would get little or no support from the actual state of the present law. We do not really know what Emotion is, though we do know how intimate are its connexions not only with the central nervous system, but also with the visceral organs of secretion and nutrition, of respiration, and circulation. The law says, "If you have an ill or prejudicial feeling towards another you must use your will to stifle it and not allow it to influence your action." How can you use your will to suppress a process which is really the chief constituent of your will at the moment? Feeling is the main constituent of Will, it is the element which turns the scale in the direction of action, and yet the law refuses to recognise affective insanity. As a learned judge once said to a celebrated lunacy expert, "When you talk of affective insanity you are talking to the wind!" Even Emanuel Swedenborg, imperfect physiologist though he was, recognised the connexion between Feeling and Will, for he says,[1] "Those things which affect a man belong to his will, and those things which a man thinks belong to his understanding. Whosoever is not aware that affection is of the will confounds affection with understanding; he says it is one thing with thought, but yet they are not one, though they act as one. That all things of the body are referable to the heart and lungs is known; but that there is a correspondence of the heart and the lungs with the will and the understanding is not known."

### BASIS OF EMOTION.

If we do not know the real nature of Emotion we do recognise that it is a quality of ideas, that certain forms of ideas have Feelings of kind associated with them, and so we speak of sad or of joyful ideas, as also of indifferent ones, in which no striking emotional tone is to be noted. Now these ideas, we must conceive, have organised physical bases upon which they must depend for their integrity, and as long as these substrata remain entire the disposition, the likes, and dislikes must remain the same. It may be possible by argument, education, or necessity to change a man's ideas and thereby to produce a preponderance of emotional tone in a direction contrary to what it was, but the old ideas with their *propria* of tone are not destroyed and usually remain in consciousness even under the new mask, whilst they materially modify any conduct which the new ideas may suggest. As the popular saying goes, "The man still remains faithful to his old love," and is easily brought back into its tracks. Suppose, however, that from disease of an irritating or destructive nature—a lesion, in fact—certain tracts of tissue become involved which are the carriers of grades of ideas with their accompanying tones, it is evident that the whole trend of nature and education may be altered and Emotions of a contrary form set up which suggestion and expostulation are incompetent to cope with. But if so, this must be due to disease or to such disuse of structure as amounts to a practical atrophy and loss of competence to function. This, then, it is which turns love to hate; not a change due to the substitution of the quality of an idea into one of an opposite kind, but the substantial obliteration of a material which functioned in a definite way and its replacement by the growth of a different set of processes.

You, then, may say that this process of changed emotion by the growth of opposite ideas of which Emotion is the appanage can surely not be distinguished from a delusion, is in fact a delusion, and must be treated as such, I repeat that I am quite prepared to grant the force of this argument, for to my mind Emotion is the local sign of the idea, and on the theory of the physical basis of mentation it is the key to the position, but to the outsider what is most striking is the loudness of the tone, and he is apt to ignore the fact that it denotes a change in the structural basis of ideas, supplemented as these must be by arguments, started from the new trend and reinforced by association and its recognised laws. Emotion is, etymologically, the moving force of the idea; more than anything else it causes the idea to issue in action—this it is which stirs in oratory, which makes the enduring obstinacy of the martyr, which forces on the impulsive acts of the murderer, and which determines the course of the social system to a greater extent than any other factor which we can adduce from the analysis of a mental content. There are persons in whom the emotional tone is feeble, and this placidity has its advantages, for it saves them from the perturbation, now on the crest of the wave of success, now in the trough of failure

[1] Divine Love and Wisdom, p. 269.

and despair, of their more sensitive compeers; it makes its possessors exponents of what is called the calm logic of facts, though it deprives them of that cataractic force which can overcome Reason by the *vis viva* of Feeling. There are many who are unconscious of the idea when in the presence of strong Emotion, and the accumulated tone when many associated ideas are acting in harmony blinds the agent to the nature of his thought and urges him to an action which, though consonant with his Feeling, is opposed to his best interests. Says King Lear:—

"The tempest in my mind
Doth from my senses take all feeling else."

Shakespeare did not know the word "Emotion," at least he never once uses it, but he was quick to recognise the effect upon consciousness of strong Feeling. I can quote the case of a man whose early life was not what it should have been, and who, being placed in a position of great responsibility, got to feel his inadequacy upon moral grounds to retain it, yet to his friends there was no insanity present; he simply said that he was depressed and made no sign, gave no outward indication by conduct or conversation. All the same, his excessive emotional tone incapacitated him from following his vocation, and whereas matters which formerly caused him not a second thought now became so obsessional as to constitute an actual derangement. "The evil that men do live after them," says our great poet—it is, unfortunately, true that on occasion it becomes dominant during life and shatters the integrity of mind as a whole, leaving an impotent detritus.

### ACTION.

If we now turn away from the subject of Emotion and take up that of Action we notice that changes in this sphere may be the only signs of insanity, but they are so urgent that it becomes necessary to act upon them, though to do so requires, at times, some courage and much daring. Action is the key to internal thought, but just as "language was invented to conceal thought," I do not mean to say that action of necessity shows all that we really think; it, in reality, may be an indication of only part of what is thought and not what is the true belief of the agent; but, even so, it is the result of a certain mental process the motives of which may not be apparent or accessible, and often are so latent that we cannot use them for our purpose when the object is to restrain the individual.

Crime of the worst kind is not always owing to insanity; indeed, many criminals are sane and clever, and their acts are the legitimate and necessary products of a sound organisation. It is a wicked and a punishable offence to kill another person for selfish purposes, but there is not necessarily any insanity in it. The deliberate murderer thinks nothing of the wickedness, and he uses all his intellect (not infrequently with success) to avoid the punishment. I am not speaking now of impulsive acts where the accession of a sudden emotion of overwhelming intensity leads to the commission of crime, but of a continued and apparently deliberate line of action, and the question arises, how are we to distinguish between acts the result of a sound, but wicked or ignorant and uneducated, mental constitution from acts which are the result of disease, but where none of the legal tests of insanity can be adduced, where there are no delusions, no hallucinations, no incoherence, no indications by conduct in the ordinary amenities of life, where the person may know not only what he is doing, but also that in the abstract he is wrong, and yet we shall be right in coming to the conclusion that he is really insane and irresponsible—that is, that he is suffering from disease or from imperfection? A concrete example of what I mean would run as follows. A man in good social position and possessed of adequate means carries on his social responsibilities with capacity and decorum for a number of years until he meets with an accident to his head. Soon after that his conduct changes, he becomes involved in dealings of a licentious and compromising character, is blackmailed, and loses large sums of money, reducing his family from affluence to narrow straits, so that the question arises as to his sanity. To talk to, the patient is coherent, gives perhaps a few sentimental reasons for his conduct, but shows no delusions; to those with whom he is casually brought into contact he is apparently quite sane. Upon these latter persons there comes one day a thunderbolt in the knowledge that lunacy certificates have been made out and that he is deprived of responsibility. When it comes to the question of regulating the administration of his property he has the power of demanding a jury, and if this is accorded all the previous work is undone, for an ordinary, or even a special, jury cannot understand that a man is insane who has no delusions and is able to answer ordinary questions. Fortunately, in most cases a jury is not demanded, and the decision rests with expert judges who know by experience that action alone may be the true test of an insanity, and that the present state of the law is not always adequate to determine these difficult cases. The best referees in these conduct cases are the general practitioners, who alone have the special opportunities formed by their medical training of correctly appreciating such aids to diagnosis as are afforded by noticing any change of temperament or of habits and customs, &c., which emphasise the conclusion that some radical defect in nervous constitution is the basis of these depraved actions.

The general practitioner as a practical psychologist, trained by experience in the school of observation, is the man in whose hands lies more than in any others the determination of the real nature of these disturbances of emotion and action, he is constantly at work in the human laboratory of causes and effects, and if to his never-ending school of phrenology he can add the analysis that training in psychology gives we have all that is required for the proper appreciation of what man is intended to be—a machine to think and to act.

### TREATMENT.

And now it becomes necessary to ask how far we can go towards the cure of the two conditions which I have been elaborating. Can these mental atoms he got at except through structure? Is there a mind apart from the body? We are calling out for something definite to go upon, and as yet all our advance is in the direction of procuring a healthy and sound structure. Strive as we will, the demonstration of mind—what is called the spiritual mind—seems as far off as ever. We talk of psycho-physical parallelism and elevate it to the rank of the most recent and scientific explanation that can be held, but the very existence of the term shows that Brain and Mind are not cause and effect, that we do really hold that there is an undemonstrated mental process apart from the body but acting through and with it. If a person comes with the complaint of change of feelings towards those who ought to be nearest and dearest, if he complains of lost power of Attention and of Will, are we simply to look for some bodily defect and direct all our energies to remedying or modifying that? At present it looks like it; but I do not hesitate to say that though we shall often be right in pointing to some diseased corporal condition we cannot always detect it, nor can we indeed be sure that in all cases it exists.

It is piteous to have to listen to the plaints of emotional stress, of want of energy, of loss of power of concentration, of insomnia, &c., and after a careful but fruitless examination of the bodily organs to find oneself unable to do anything to relieve the condition beyond advising change of scene or such gross temporary expedients as sedatives and narcotics. We feel that we should like to get hold of that spiritual mind and compel it to a proper influence, but even if we could we have no pharmacopœia of remedies for it. We are tortured by discordant strains and on looking for the cause we find that the instrument is in perfect order but that it is the performer who is at fault. Where is the performer on the brain instrument? No doubt the performer is often eager—oh! so eager—to have the instrument altered to his requirements, chafes at the defect which converts his best wishes to unsupportable discord, but is this always the case? Is not the performer frequently at fault, though we cannot unseat him? Mr. Ballance told me of a boy, an incorrigible thief, who was completely cured of his bad habits by the operation of trephining. Whether the operation was successful by relieving pressure I do not know, but anyhow it was an extraordinary result to obtain a complete change in mental trend from an alteration in physical conditions. I once had a case of a lady who gave utterance to the most fearful delusions of the persecution kind and was grievously depressed. She had an attack of erysipelas, and during the course of the disorder her depression and delusions completely disappeared, and she was perfectly sane. Was the insanity of this lady due to brain disorder (perhaps of a toxic nature) which was for the time cured by the presence of new micro-organisms?

Perhaps; but if so it points out how long-continued disordered brain action may exist without radical impairment of tructure.

It was hoped that some progress was being made in our knowledge of the nature of mind when the study of psychophysics was introduced, but the results, though very interesting as regards the way in which bodily processes and mental phenomena interact, can scarcely be said to have enlightened us on the real question. Some time ago Wundt of Leipzig, in discussing Weber's and Fechner's laws, made the following statement: "Not only have we discovered the law of the dependency of sensation upon stimulus, but we have indicated the method by which the intensity either of sensation or of stimulus can be calculated when the intensity of its correlate is given. The method is simplicity itself, for it presupposes no more knowledge than the multiplication-table and no more apparatus than a book of logarithms"—and very much the same may be said of Ebbinghaus' law of memory. But after all this is only another way of regarding the same thing, and it does nothing in the way of showing us the real nature of the mental processes. And yet in the face of some apparent successes it does not seem right to let the mental symptoms follow their own course without some attempt to check or to modify them, after we have definitely concluded that there is no structural defect in the nerve centres and tracts. I come across people who are quite well as far as can be ascertained in their bodily processes, and yet who suffer intensely. At present suggestion, with or without hypnotism, seems to do more good than anything else. I have known a lady cured of insomnia, depression, and headache by the very natural process of having a baby. Was this a physical cure (in a way which certainly cannot be understood) or was it a mental cure, by giving her something to think about in place of the *ennui* of uneventful married life, thus providing occupation and mental relief?

We know the curative effect of time upon emotional states, how the most poignant grief (and this without any marked structural process) degenerates into an easily portable placidity merely by the action of a moderating influence, which, whilst leaving intact the idea, robs it of emotional sting. You may say that through the agency of time the idea has lost its intensity through diversion of tracts to some other quarter, but this is not so, because we can prove that the idea remains in all its vividness and can be as fully discussed as ever, but it has lost its tone—it no longer affects—in a word, its accompaniment of Emotion has left it for ever.

I am not without confidence in affirming that notwithstanding the general despair as to success in improving mental symptoms when simply physical treatment seems useless there is yet ground for the belief that we may do good service by a system of mental training; but constant and personal attention is indispensable, and the process is apt to be tedious and is certainly expensive.

Perhaps I may for a moment refer to the very proper insistence made by the Lunacy Commissioners against the too common practice of placing very large numbers of insane persons under limited medical supervision. It is argued, and in my opinion correctly, that persons gradually lapse into a state of dementia because such mental energy as remains is neglected, and that if individual attention could be given the revival of nervous energy would be assured. Of the truth of this I am certain. I have often taken in hand apparently hopeless cases, and by regularly talking to them and trying to arouse dormant mental states I have succeeded in replacing listlessness by energy, apathy by attention, and impulse by deliberate will action.

In dealing with private patients the importance of small homes cannot be exaggerated, and, if possible, change of surroundings should be given, because the patience of an individual becomes weakened by too continuous effort and there is novelty in change. Where, as in public schools, there is a very large number of pupils the indifferent plodders are apt to go to the wall and only those of brilliant promise are selected for special exhibition, so is it in overcrowded establishments—those of ponderous inactivity are left to their broodings, and recovery is blighted where a timely and continual stimulus might be of inconceivable value.

It is above all things necessary in treating cases of emotional alteration to place them in new surroundings, away from family influences, to persist in methods calculated to arouse new ideas with their own peculiar emotional tones, so as to let the old ones starve by inanition—not so much to leave the individual to fight his own morbid thoughts (a process which often tends to emphasise the disordered function, because the very fact of trying to overcome it keeps strongly in consciousness the one thing which we are seeking to weaken)—not, I say, to leave the patient alone to struggle with his obsessions, but to take away ourselves the weight from him, to release him of the burden which he vainly tries to shuffle off. It is in this way that Suggestion becomes a powerful agent, not by pooh-poohing certain painful feelings and saying that they do not exist, but by ignoring them and setting up other strong tones, whilst we allow Time to aid us in subduing old influences. The patient must be kept going in new tracks, whilst the old footsteps are gradually made faint, not by his own scattering of oblivious sand, but by a gradual and final desuetude. This is the *rationale* of Freud's treatment, and it is easy to perceive how long and tedious the cure may be.

If by these means we can set up a change in the emotional tone it is but a step further to obtain success in increasing Inhibition, in strengthening the Will, because as new processes are set up so do the old constituents of the old Will fade and a new Inhibitory power is inducted. We do not call upon the patient to exert a Will which by its essential composition is a part of the same morbid process as the Emotion, but we try to induce a new Will in harmony with the new emotions which we are seeking to arouse, a new Inhibitory Force which shall so uproot past troubles that their very existence is a lost memory. I have noticed with this emotional change that there is often an irritability of general demeanour, patients become peevish and discontented, a state compounded of despair and anger; they go from one practitioner to another, are told that there is nothing the matter with them and that it is merely a case requiring time. Then, finding that they do not get well, they naturally become hopeless and desperate, unbearable to themselves and others.

It is a mistake to tell these people that there is nothing the matter with them. Is it likely that they delight in spending their money on medical men, in the gloom of separation from amusements and family duties? What they want is disciplined treatment, not the ordinary form of rest-cure, but residence in good hygienic conditions under some one who, whilst having plenty of sympathy, can mix it with firmness and authority, so as to check the ramifications of disordered Feeling and make the patient feel how to help himself.

You will notice that it is chiefly among the better classes that the symptoms of which I have been speaking occur; the lower classes do not suffer so much in this way; they have occupation all the day long; they have large families and are not dependent on the theatres and the golf-clubs for their diversions; for these Time is all too short, for the others it is too long and tedious. You have only to turn to the law reports to see how responsible are the sudden outbursts of Emotion for crimes of all kinds—blind fury, the hasty deed, unconsciousness of all process of thought at the time, then the hasty repentance, and to all this the law is blind as regards mitigation—says, in fact, "That is what I am here for—to check." Then comes the reign of Lust and Desire, leading to the destruction of everything that stands in the way of gratification. Again says the law, "This I am here to punish." And so the thing goes on. Reputations are ruined, contracts are broken, selfishness becomes the keynote of life because of the perversion of Emotion, which as it is the goal of the many who seek happiness as the *summum bonum*, so does it become the trapdoor through which many numbers fall in their journey across the bridge of Life.

---

THE INTERNATIONAL MEDICAL ASSOCIATION TO ASSIST IN THE SUPPRESSION OF WAR.—This association will assemble in congress during September, 1911, in Paris, at a date which will be fixed later and which will be communicated to all those interested. The medical men who desire to attend this Congress are asked to be good enough to send in their adhesion, as soon as convenient, to the headquarters of the association, at the address of the Président, Docteur J. A. Rivière, 25, Rue des Mathurins, Opéra-Paris.

# The Hunterian Lectures

ON

# COLOUR VISION AND COLOUR BLINDNESS.

*Delivered before the Royal College of Surgeons of England on Feb. 1st and 3rd, 1911,*

BY F. W. EDRIDGE-GREEN, M.D. DURH., F.R.C.S. ENG.,

BEIT MEDICAL RESEARCH FELLOW.

## LECTURE II.[1]

*Delivered on Feb. 3rd.*

### THE DETECTION OF COLOUR BLINDNESS FROM A PRACTICAL POINT OF VIEW.

#### I. *Object of a Test for Colour Blindness.*

GENTLEMEN,—Tests for colour blindness are of two kinds—namely, those which are used for the purpose of ascertaining the special phenomena of colour blindness, and those which are employed when the inquiry is made for some practical purpose. As with visual acuity, it is necessary to fix an arbitrary standard. As we do not wish to exclude a greater number than is absolutely necessary, the object of the test should be to exclude dangerous persons, and dangerous persons only. These persons may have other duties to perform which do not require them to possess a perfect colour sense. I should, however, like to see those persons who are specially qualified for a certain position occupy it; for instance, men who had to keep a look out on our most important ships being selected because of their accurate colour vision and visual acuity. I do not mean that I would select only those men and reject the others, but that I should like to see a second object of a test—namely, to select those who are specially efficient so that the captain might know on whom to rely in conditions of exceptional difficulty.

#### II. *The Requirements of a Test for Colour Blindness.*

A test for colour blindness when it is to be employed for some definite and specific purpose, as, for instance, excluding dangerous persons from certain callings, should be such as to show definitely that the persons rejected are dangerous. It is very useful to demonstrate to the men and their fellows that a rejected candidate is dangerous. The colleagues of a rejected candidate would refuse to risk their lives with a man who before their eyes called a red light green. I was expressing these views when a superintendent of a railway company who is using my lamp told me that he had adopted this method with great satisfaction to himself and to the men. A man, for instance, who has been working 20 years on the railway has been rejected for colour blindness. He has complained bitterly to the superintendent, at the same time declaring emphatically that he is normal sighted. The superintendent has replied, "You know red?"—"Yes." "You know green?"—"Yes." "You will therefore agree that if you call green red or red green you ought to be rejected. Bring two or three of the other men in with you and I will test you." The man has readily agreed to this. The superintendent has then tested him by asking him to name various coloured objects in the room, and knowing by experience exactly the coloured objects which are miscalled by the colour blind readily exposes his defect. It is noteworthy that on some occasions a colour-blind man has been tested by another person in the same room without making any of the mistakes which he subsequently made, because none but coloured objects which he could readily recognise were shown to him. This is an example of the necessity of a practical knowledge of colour blindness in an examiner. On account of the arrangement of signals by sea and land it is necessary that persons employed in the marine and railway services should be able to recognise and distinguish between the standard red, green, and white lights in all conditions in which they are likely to be placed. An engine driver or sailor has to name a coloured light when he sees it, not to match it. He has to say to himself, "This is a red light, therefore there is danger"; and this is practically the same as if he made the observation out loud. Therefore, from the very commencement we have colour names introduced, and it is impossible to exclude them. The engine driver is told that red is a "danger" signal, green a "caution" signal, and white an "all right" signal. Therefore it is absolutely necessary that he should know the meaning of these colour names. A test should be such as to make it impossible for the examinee to be coached through it. This is one of the most important requirements of a test for colour blindness, and one that is rarely fulfilled. Nearly every one of the tests in general use fail on this account.

A test should be one which can be carried out as rapidly as is possible with absolute efficiency; of two equally efficient tests the one which takes the least time must be selected. A test, therefore, should have no unnecessary details which, though of theoretical interest, are not concerned with the object in hand. The test should be made as easy and as little complicated for the examiner as possible.

#### III. *Persons to be Excluded.*

We wish to exclude all those individuals who are included in the following three classes: (1) those who see three or less colours in the spectrum; (2) those who, whilst being able to perceive a greater number of colours than three, have the red end of the spectrum shortened to a degree incompatible with their recognition of a red light at a distance of two miles; (3) those who are unable to distinguish between the red, green, and white lights at the normal distance through defect or insensitiveness of the cerebro-retinal apparatus when the image on the retina is diminished in size.

I will now explain why these three classes of persons should be excluded. The first class includes the trichromic, the dichromic, and the totally colour blind, in accordance with the facts previously stated. The trichromic never, in ordinary circumstances, mistake green for red, but confuse yellow with green or red. Colour is a feeble quality of objects to them, and nervousness or excitement may reduce them to the condition of the dichromic. The dichromic are liable to mistake a green light for red and *vice versâ*. It is very important that persons belonging to the second class should be excluded, and yet none of the ordinarily used tests detect them. The rays of red at the extreme left of the spectrum are the most penetrating, as may be seen by looking at a light or the sun on a foggy day, or through several thicknesses of neutral glass. It is chiefly by these rays that we recognise a red light at a distance; and it is therefore of great importance that a sailor or engine-driver should be able to perceive them. The third class contains persons who are able to distinguish colours easily when they are close to, but fail to distinguish them at a distance owing to the nerve-fibres supplying the central portion of the retina being impaired. As a light at a distance occupies the central portion of the visual field it is essential that the corresponding portion of the retina should be normal. There are cases of central scotoma for colours with perfect form vision; these would therefore not be detected by the test for visual acuity. This class also includes those who without having a scotoma are unable to distinguish between colours at the normal distance when the image on the retina is diminished in size.

#### IV. *The Construction of a Test for Colour Blindness.*

In the construction of a test for colour blindness the facts of colour blindness must be utilised so that the object and requirements of the test are fulfilled. The following facts are of practical importance.

1. *Most colour blind make mistakes with certain colours, but are correct with regard to others.*—This may be illustrated in the following way. Let us take an ordinary dichromic, and having given him the set of wools belonging to the classification test ask him to pick out all the reds. On examining the pile of wools selected as red it will be found that the majority are red, but in addition there will be some browns and yellow-greens. If he be then told to pick out the whole of the greens the greater number of those selected will be green, but there will be also greys, browns, and reds. In

[1] Lecture I. was published in THE LANCET of Feb. 4th, p. 285.

each case it will be seen that the majority of wools are of the desired colour.

If another dichromic be examined in the same way it will be found that, though he may not make exactly the same mistakes, he will in all probability pick out the same greens to put with the reds and the same reds to put with the greens. The same result will be obtained if the colour-blind persons be asked to name a large number of colours. They will in most cases name the colour correctly. It will be noticed that the greens which were put with the reds when classifying the colours will be called red in naming them. It is evident that the same idea has guided the colour blind in each case. This shows that, though a person may be red-green blind, he is not absolutely red-green blind in the sense of being totally unable to distinguish between the two colours. The fact that they are actually judging by colour may be demonstrated by giving them coloured materials of different kinds or by asking them to name a large number of coloured objects.

It will be seen that if we take a dichromic and ask him to name a number of red and green wools, in the majority of instances he will name them correctly. But as, almost invariably, the same wools are chosen, for all practical purposes the same result would be obtained by asking a person to name a few of these wools. What more decided and brighter greens could we have than Nos. 76 and 94 of my Pocket Test? Yet these are two of the greens which are called reds by the dichromic. We should have accomplished as much by asking a colour-blind person to name Nos. 76 and 94 as if we had asked him to name a large number of greens. The colours in a test should, therefore, be those which the colour blind are particularly liable to miscall. At the same time, their nature should be unmistakable to the normal sighted.

2. *The colour blind name colours in accordance with their colour perception, and thus show definitely to which class they belong.*—I have not come across a man who has guessed correctly when examined with my test. A man who did guess would know that he was incompetent. As the colour blind are often not aware of their defect they answer as they see, only guessing when they feel uncertain as to the nature of the colour shown. There is probably more misapprehension on this point than on any other in the practical testing of colour blindness.

3. *Colours may be changed to the colour blind whilst leaving them unaltered to the normal sighted.*

4. *The phenomena of simultaneous and successive contrast are much more marked for the colour blind than for the normal sighted.*—Two colours, which have not changed in the slightest degree to the normal sighted on being contrasted, have apparently altered very considerably to the colour blind. As an example of this, let us take a pure deep yellow, a bright red, and a bright green. To the normal sighted the yellow will be altered very little by comparison with the red or the green, but a trichromic would say that the colour was green when contrasted with the red, red when contrasted with the green. This principle of exaggerated contrast must be borne in mind when examining a candidate. Thus, if a trichromic be doubtful about a yellow, but seems inclined to call it green, he should be given a pure green to compare with it. In the same way, in showing the coloured lights the same colour produced in a different way should often be shown. Thus, an orange-red may be shown immediately after a pure red. This will not alter the colour to the normal sighted, but greatly facilitate the examination of the colour blind.

5. *Many colour blind match correctly but name the principal colours wrongly.* Therefore the test must be a naming test, the examinee being rejected if he confuse the colours which it is essential he should distinguish between in his occupation.

6. *Many colour blind recognise colours easily when they are close to them or the surface is large, but fail to distinguish between them when they are at a distance or the image on the retina is small.* The test must be constructed in conformity with these facts.

7. *The colour blind are more dependent upon luminosity than the normal sighted, and are liable to mistake a change in luminosity for a change of colour.* The test should have a means of rapidly changing the luminosity of a colour.

8. *The colour blind find special difficulty with faint and dim colours.* The test should have colours of this kind.

9. *The colour blind who have shortening of the red end of the spectrum cannot see reds reflecting or transmitting only rays corresponding to the shortened portion.* It is essential that reds of this kind should form part of the test.

10. *The colour blind find more difficulty in comparing colours when different materials are used than when the coloured objects are all of the same nature.*

11. *Most colour blind find more difficulty with transmitted than with reflected light.*

12. *The colour blind have a defective memory for colours.*

13. *Colours may be changed to the normal-sighted whilst leaving them unchanged to the colour blind.*—When three colours of the normal-sighted are included in one of the colour blind, it is obvious that a change from one colour to another of the three will make no difference to the colour blind. Also, when the spectrum is shortened the addition of rays corresponding to the shortened portion to another colour will not alter its appearance to the person with the shortened spectrum. For instance, to a person with shortening of the red end of the spectrum a blue will still remain blue when so many red rays from the shortened portion have been added to it as to make it appear rose to the normal sighted.

14. *The colour blind may have a sense of luminosity similar to that of the normal sighted.*

15. *The dichromic distinguish between the colours of the normal sighted which are included in one of theirs by their relative luminosity and the difference of a saturation which is apparent to them.*—A test should therefore have the means of presenting colours of different saturation in succession. Colour blindness is often associated with exceptional intelligence and ability.

### V. *The Lantern*[2] *Test.*

1. *Description of apparatus.*—The lantern contains four discs: three carrying seven coloured glasses and one with seven modifying glasses. Each disc has a clear aperture. The other mechanical details are: an electric or oil lamp with projecting accessories, a diaphragm for diminishing the size of the light projected, handles for moving the discs and the indicator showing the colour or modifier in use. The diaphragm is graduated in respect to three apertures to represent a 5½ inch railway signal bull's-eye at 600, 800, and 1000 yards respectively when the test is made at 20 feet. The glasses are as follows:—

| Coloured glasses. | Modifying glasses. |
|---|---|
| 1. Red, A and B. | 7. Ground glass. |
| 2. Yellow. | 8. Ribbed glass. |
| 3. Green. | 9. Neutral (No. I.). |
| 4. Signal green. | 10. Neutral (No. II.). |
| 5. Blue. | 11. Neutral (No. III.). |
| 6. Purple. | 12. Neutral (No. IV.). |
| | 13. Neutral (No. V.). |

It will be noticed that three of the discs are similar in every respect. In some of my lanterns the two reds are put at the end of the series of colours and numbered Red 1 and Red 2. This makes no important difference, but the arrangement given here is more convenient. It should be noted that Red 1 corresponds to Red B and Red 2 to Red A. If the electric lamp should get broken the projecting apparatus can be removed and an ordinary kerosene lamp placed behind.

2. *Reasons for special construction.*—The lantern has been constructed conformably with the requirements and facts of colour blindness. All the facts I have given have been considered in constructing the lantern.

The examiner on possessing a lantern for the first time should carefully test himself with it and ascertain how the different lights appear to him with different conditions of general illumination. It is probable that certain improvements may suggest themselves to him; therefore, I think it will be advisable to deal with certain of these points, as it will help the examiner in the use of the lamp. The colours have never been altered and I certainly should have altered them if I could have improved the lamp by doing so. I have never met with a single colour-blind person who has not been readily and easily detected with my lantern though I have examined many who have passed other lanterns and in some cases a number of other tests for colour blindness. In most cases one turn of the wheel will be sufficient to make a colour-blind person disclose his defect.

The examiner may be dissatisfied with the colour of the blue, let us therefore compare an examination of a normal-

[2] Made by Reiner and Keeler, 9, Vere-street, London, W.; and Meyrowitz, 1A, Old Bond-street, London, W.

sighted person with that of an ordinary dichromic. The normal-sighted person will name every one of the colours with ease and certainty, with perhaps the exception of the blue, with which he is in some doubt. Here is the result of an examination of an ordinary dichromic: he called the yellow, green; the green, red; the signal green, no colour; the blue, blue; the purple, green; red A, no colour or light; red B, green.

It will be noticed that the only colour that he has correctly named is the blue. We can try him again and again, and though he will mistake all the other colours he will always name the blue correctly. The examiner will have learnt from this several important facts. He will see that the colour blind are really guided by their sensations of colour and that it is not simply a matter of guessing. The more an examiner has practical experience of colour blindness the more will he recognise the fact that the colour blind are guided by their sensations of colour. He will notice that the dichromic has readily recognised the blue which was scarcely apparent to him (the examiner), and therefore cannot have overlooked as a matter of carelessness colours which are much more apparent to the normal sighted. The blue is a valuable colour for other reasons, for though it is not a colour on which I reject candidates, anyone miscalling it must be very carefully examined before he is passed. The trichromic generally call this blue, green. If we wish to obtain a purer blue we can do so by combining the blue or the purple with the signal green.

Again, the examiner may think that it might be better to have an apparatus which showed two or three lights instead of only one; I will therefore give my reasons for adopting only one. This point was one which occupied my attention for a considerable time, especially in view of the fact, which, as far as I am aware, I was the first to discover, that simultaneous contrast is increased to the colour blind. I was naturally anxious to turn this fact to account. I found, however, that I gained nothing by increasing the number of lights, and that in many cases it was a source of error. A second or third light could have been easily added to my lantern, but besides unnecessarily complicating the apparatus it would have served no useful purpose. All the results which are obtained with simultaneous contrast are obtained even more effectively with successive contrast. It will be noticed that when lights are seen in ordinary conditions, they are conditions of successive contrast and not of simultaneous contrast. An observer rarely keeps his eyes definitely fixed on one light whilst he names those adjacent to it, but moves his eyes so that the images of the respective lights fall successively on his foveas. When more than one light is employed all the disadvantages of matching as against naming are introduced. It will be seen that by presenting one light after another we are fulfilling all the necessary conditions, only that the light is moved instead of the eyes, sufficient time being allowed to elapse to enable a normal-sighted person readily to recognise the true colour of the next light without being confused by the after-image of the one he has just seen. Many nervous normal sighted would name a yellow light seen between two red lights as green, and it does look green to them from ordinary physiological conditions. They look first at one red light, then immediately at the yellow light, then at the second red light, and then again at the yellow light until they feel sure that the centre light is a green light and say so. I have never met with a normal-sighted person who has miscalled the yellow light of my lantern either red or green. Many humble nervous normal-sighted persons are under the impression that they are colour blind and yet would make perfectly efficient officers. Many of these men have been told by their wives or other persons that they are colour blind, and believing this try to see colours which are not visible to them. I have examined many persons of this description and have noted the ease and accuracy with which they have gone through the tests for colour blindness when they have been assured by me that they were normal sighted. On the other hand, it is often very difficult to convince a self-reliant colour-blind person that he is colour blind. He is on the look-out for the small differences which he notices between colours, and the fact of having another light for comparison gives him the desired clue, and though colour blind he passes the test.

The material is the best possible, as it will not fade like all dyed substances, and therefore all records made with one set of apparatus will be uniform. Again, a coloured light has none of the accessory qualities which enable the colour blind to pass through other tests. Thus many dichromics will call the yellow glass red or green, who would not think of putting a yellow with a green or red wool, on account of the difference in luminosity. He will in the same way if told to pick out colours in the Classification Test to match the colour of the light shown, have to depend upon his colour perception. This is a useful method with nervous and undecided candidates. The objection to it is that it cannot be carried out in the dark room. The test is not open to any of the objections which may be urged against the method of simply naming colours, because the character and intensity of the colour may be changed at will.

The method is better than that of direct comparison, because the candidate is forced to use his colour perception and has to compare the colour seen with previous impressions of colour in his mind. By the use of neutral glasses, &c., I have obviated the fallacy of the method of naming colours—namely, that these can be distinguished by their saturation and luminosity—and forced the individual to depend upon his colour perception and not upon some other accessory quality of the object seen.

No amount of coaching will enable a colour-blind person to pass this test, whilst almost any other may be passed in this way. I have tried on many occasions to coach a man so as to pass my lantern and without success. The combinations are so numerous that the only result is to make the colour-blind man nervous and doubtful and more easily detected than before. This has occurred with men who could pass other tests with ease. The test, also, has a quality possessed by no other—namely, that of enabling the examiner to reject dangerous persons, and dangerous persons only, the lower degrees of colour blindness being allowed to pass.

3. *Special directions for conducting the test.*—1. The candidate should be seated at a distance of 20 feet from the lantern. 2. He should be asked to name the colour of the light produced by a coloured glass (1 to 6) alone, or in combination with another coloured glass or glasses, or with the modifying glasses (7 to 13). 3. A candidate should be rejected (*a*) if he call the red green, or the green red, in any circumstances; (*b*) if he call the white light, in any circumstances, red or green, or *vice versâ*; (*c*) if he call the red green, or white lights black, in any circumstances. 4. A candidate who makes mistakes other than those mentioned above should be put through a very searching examination. It is not necessary to have the room absolutely dark; in fact, I prefer a certain amount of light. The examiner can, if he wish, make the test at night in the open air.

The examiner should on no account conduct the examination on any regular plan, because the candidate, anxious to pass, finds out from persons who have already passed, the order and method of examination, and so, though colour blind, might obtain a certificate. Any one of the glasses may be shown first, and the candidate required to name the colour of the light. The following will serve as an example of the method to be employed in testing a candidate. A red being shown, the candidate is required to name its colour. Then a blue or green may be substituted. It is best to use the largest aperture at first and to show all the colours on one disc. This will give confidence to the normal-sighted candidate, whilst most of the colour blind will be detected. In the case of candidates who appear to be normal sighted and yet very nervous there is no harm in telling them after they have named all the colours on the disc correctly that this is the case. No comment should, however, be made on individual answers. Then one of the neutral ground or ribbed glasses should be inserted, not the slightest intimation being given to the candidate of the nature of the colour. He should be asked to name or describe the light, and the answer, if incorrect, together with his other replies, carefully recorded. The other glasses may then be shown, a combination of the neutral, ground, ribbed, and coloured glasses being used at irregular intervals.

When the candidate has been examined with the largest aperture the examiner can go through the same procedure with one of the smaller apertures. I have found the third aperture the one which is most generally useful. On account of the great diminution of total luminosity caused by

the diminished area of the light source, the three smallest apertures can only be used in a dark room.

If a candidate hesitate about a colour and ultimately name it correctly, a second, and if necessary a third, glass of the same colour should be combined with the first. The fact that in one case a single glass is used and in another two or three of the same coloured glass makes very little difference in the colour of the light to the normal sighted. This is not the case with the colour blind; a dichromic who has hesitated about a green and then correctly named it may emphatically call the light red when another green glass is put in front of the first.

Care must be taken when the candidate is going to be examined with two glasses at once, such as one of the neutral, ground, or ribbed glasses, and a coloured glass, that he does not see the light until both are in position, or else he may see the colour before it is modified in the necessary way.

If the candidate call the standard red green, or the standard green red, in any circumstances—that is, either alone or in combination with the modifying glasses—he is to be rejected.

The examiner should ascertain for himself how far the various colours are visible when modified with the neutral glasses. If the red and green be not visible with the thickest neutral, in the conditions of luminosity and external lighting which the examiner is employing he should use the darkest neutral which allows the colours to be plainly visible to the normal sighted. In all cases of doubt the examinee should be asked to walk towards the lantern and told to say when the light is visible and asked to name its colour. The distance at which the light is visible and then that at which the colour is visible should be noted and compared with the normal.

Particular attention should be paid to the answers given to the combination of the thickest neutral glass with the standard red and green respectively.

The examiner should utilise the fact that successive contrast is increased in the colour blind as this is an easy method of detecting the trichromics. The red having been shown the light should be quickly changed to yellow or clear, the examiner's hand being placed over the aperture if there be any intervening colours. It is necessary that the yellow should be shown immediately after the red without any intervening colours being first seen by the candidate. The normal sighted do not see any change in the yellow or clear when they are shown after the red light, but the trichromic call the yellow light green. The examinee should then be shown the green light and then the yellow or clear in the same way as mentioned for the red. The normal sighted will easily recognise the yellow, but the trichromic will call it red. This portion of the examination must never be omitted in any examination in which the candidate is passed. The two divisions of the test—that is, showing yellow immediately after red and after green—may be used at different periods of the examination, and if there be any doubt repeated.

An examiner should, as far as possible, with the exceptions given in the instructions, avoid all conversation with the candidate, simply asking, "What colour is this?" and recording the answer without comment. If an examiner after each answer say, "Quite right," or some such expression, the following is likely to occur. The candidate after, say, six correct answers makes a mistake; the examiner says, "Are you sure?" Then the candidate knows at once that he has made a mistake, and makes a guess, very probably a correct one. When a similar colour is shown subsequently he remembers the mistake he made and gives the second, and probably the correct, answer.

In addition to being an efficient test it is a very rapid test, as many men who have been certified as normal after a lengthy examination with other tests have at once disclosed their defect by calling the green light of the lantern red. Many are under the impression that in an examination with the lantern the dichromic simply guess. This is entirely wrong. A man who did guess would know that he was incompetent. I find that men have named the coloured lights in strict accordance with their colour perception. A man may, however, guess if examined by an inexperienced and ignorant examiner who, when the examinee has made a mistake, promptly corrects it in a cross tone. A normal-sighted person will guess when examined in this way. The examiner must receive the examinee with a smiling face and courteous manner and appear pleased and satisfied with the answers, no matter what they may be. The candidate is then placed at his ease and answers according to his colour perception. It will be noticed that the lantern detects those who have a slightly diminished colour perception as well as the dangerous varieties of colour blindness. The former undoubtedly are not as efficient as those who have a normal colour perception, so that a definite standard will have to be fixed as in the case of visual acuity. Further details will be found in my book on colour blindness.[3]

*Summary of method of examination.*—1. Show all the colours on one disc with the largest aperture. 2. Show the reds, greens, and yellow modified by the neutral glasses. 3. Show all the colours on one disc with number 3 aperture. 4. Show red, then immediately afterwards yellow with largest aperture. Then show green and yellow immediately afterwards. 5. Test the candidate with the red, green, and yellow with the smallest aperture. 6. Show the neutrals or ground glass alone. 7. Show blue made by combining blue or purple with the signal green. 8. Show a colour, for instance, green, and then combine another glass of the same colour. 9. Show the red produced by the combination of purple with red A. 10. Give the combination of red A and signal green.

### VI. *Other Tests for Colour Blindness.*

I have three other tests for colour blindness—the classification test, the pocket test, and the colour-perception spectrometer. I have also devised an instrument for estimating the exact amount of red, at different wave lengths, which is necessary to neutralise the complementary in different persons.

1. *The classification test.*—(*a*) *Description.*—This test consists of four test colours and 180 confusion colours; 150 coloured wools, 10 skeins of silk, 10 small squares of coloured cardboard, and 10 small squares of coloured glass. The whole series of colours is represented. In addition, there are a large number of colours which have been chosen by colour-blind persons as matching the test colours. The test colours are orange, violet, red, and blue-green, labelled I., II., III., and IV. respectively. The colours are chosen with the view of presenting as much difficulty as possible to the colour blind and as little as possible to the normal sighted. The colour blind find especially difficulty in matching or naming a colour lying at the junction of two of their colours. As the normal sighted often find difficulty in saying which colour predominates in a blue-green, so do the tetrachromic with their purple-green, or the trichromic with their red-green. A colour-blind person may, however, match a colour correctly which corresponds to the centre of one of his colours. In addition to choosing those colours for tests which are particularly liable to be mistaken for other colours by the colour blind, I have used coloured materials of different kinds—wools, silks, glass, and cards—so as to force the colour blind to judge by colour, and not by saturation or luminosity.

(*b*) *Method of examination.*—The candidate should be given the four test colours, and, having named each, he should be told to select all those which are similar in colour to the test colour. He should be told to pay no attention to the fact of a colour being lighter or darker; as long as it is the same colour it should be put with the test skein. The examiner should not go through the test before the candidate first of all, neither should one candidate be allowed to watch another making his selection. A shrewd colour-blind person might pass the test if he had seen a normal-sighted person go through it previously. In order to show the candidate the difference between a shade and a colour the examiner should take one of the wools which is not a test colour—blue, for instance—and pick out four or five shades of the colour. The wools should be arranged without the knowledge of the candidate, so that a yellow or a grey is placed beside a red and the examinee asked to name its colour. At another period of the examination the yellow should be placed adjacent to a green and the examinee again asked to name it.

The examinee may pick out a certain number of colours correctly and then stop, saying that there are no more exactly like the test colour. This may embarrass the examiner; he should, however, examine any candidate who

[3] International Scientific Series, Kegan, Paul, and Co., 1909.

has omitted any colours as carefully as if mistakes had been made. He should ask the candidate to match one of the omitted colours.

The examiner will soon find out from experience those colours which are named and matched wrongly by colour-blind persons; he should ask the examinee to name some of these colours.

Any candidate should be rejected who calls an orange or red, green or brown; black, red, or *vice versâ;* or green, either purple, rose, red, grey, brown, or violet. Similar mistakes in matching necessitate objection. A candidate who puts purple, rose, or blue with violet, or yellow-brown with orange is most probably dangerously colour blind and should be very carefully examined. There are cases which pass the Holmgren test with ease that fail in the most conclusive manner with my classification test. They put green with orange, brown and black with red, and grey with blue-green. This is due to a different selection both of test colours and confusion colours. Orange is by far the most important test colour and its confusion with green by the dichromics is very conclusive. The three other test colours —violet, red, and blue-green—represent both ends of the spectrum and the neutral point in dichromic cases, and practically these colours are those with which most mistakes are made. This test can only be regarded as supplementary to the lantern test.

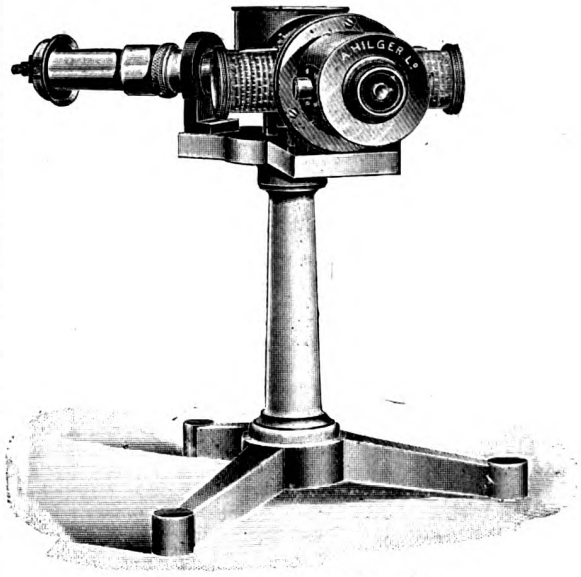
2. *The pocket test.*—This consists of 19 cards on 9 of which are 112 single threads of wool and 14 pieces of twisted silk similar to those in the Classification Test. These are numbered consecutively, with the exception of the first thread of the first four cards and the last thread of the next four cards. The end threads of the first four cards I. to IV. form the tests; they are orange, violet, red, and blue-green. There are also cards on which red, orange, green, blue, violet and purple, and grey respectively are to be found. There are also two special cards marked "Without Red" and two special cards marked "Without Green."

Many normal-sighted persons might object to the inclusion of some of the colours on the orange card, but this card clearly shows the colours which may be taken as a match. Fine distinctions are not wanted. The series of colours I have selected and arranged so as to confuse the colour blind and force them to be guided by their colour perception, whilst the quantity of colour is amply sufficient for the normal sighted to pick out the colours with the greatest ease. The cards should be arranged irregularly on a white cloth in a good light. The two most important test colours are the orange and violet, Nos. I. and II. The person examined should be asked to point out the shades of colour similar to No. I (orange). A piece of paper rolled to a point should be used for this purpose. If he does this correctly he probably possesses normal colour perception. If, however, he matches the test with reds or pinks he is more or less colour blind, at best belonging to the pentachromic class. If, in addition, he matches the violet test, No. II., with blue, he at least belongs to the tetrachromic class. The trichromic, in addition, may match the blue-green test, No. III., with brown and grey. The dichromic will match the orange test, No. I., with yellow-green and yellow-brown. Similar mistakes will be made to those described in connexion with the Classification Test. The examinee should be asked to name all the colours on one of the cards. He should also be asked to point out on which of the cards the four test colours are to be found and which contain none of the test colour. The examiner should continually change the order of the cards. Most of the varieties of the colour blind will be readily detected in this way.

The special advantages of this test are: 1. The colour blind can be ranged definitely in their proper classes. 2. Central scotoma can be detected with its aid. 3. The series of colours are arranged so as to confuse the colour blind, whilst the normal sighted easily match the test colours. 4. On account of the introduction of different materials the relative luminosity and saturation of colours does not serve as a guide to the colour blind. 5. Portability. 6. The wools and silks are kept clean. 7. An important colour is not likely to be lost.

3 *The colour-perception spectrometer.*[4]—(*a*) *Description of apparatus.*—This instrument is a spectrometer so arranged as to make it possible to expose to view in the eyepiece the portion of a spectrum between any two desired wave-lengths (Fig. 1). In the focal of the telescope are two adjustable shutters with vertical edges; the shutters can be moved into the field from right and left respectively, each by its own

FIG. 1.



The colour-perception spectrometer.

micrometer screw, and to each screw is attached a drum (Fig. 2), the one being on the right and the other on the left of the telescope. On each of these drums is cut a helical slot in which runs an index, and the drum is engraved in such a manner that the reading of the index gives the position in the spectrum of the corresponding shutter in wave-lengths direct. Thus it will be seen that if, for

FIG. 2.

Drum attachable to micrometer screw.

instance, the reading on the left drumhead is 5320, and that on the right drumhead is 5920, the region of the spectrum from wave-length 5320 to wave length 5950 is exposed to view in the eyepiece.

(*b*) *Directions for using the instrument.*—It should be used, as far as possible, with a known quality and intensity of light. A small oil-lamp is quite suitable for the purpose. The observer should first ascertain the exact position of the termination of the red end of the spectrum, the left-hand shutter being moved across until every trace of red just disappears. The position of the pointer on the left-hand drum is noted and the wave-length recorded. The left drum is then moved so that the shutter is more towards the middle of the spectrum. The right-hand drum is then moved until the pointer indicates the wave-length recorded as the termination of the red end of the spectrum. The observer then moves the left-hand shutter in and out until he obtains

[4] Made by A. Hilger, 75A, Camden-road, London, N.W.

the largest portion of red, which appears absolutely monochromatic to him, no notice being taken of variations in brightness, but only in hue. The position of the index on the left-hand drum is recorded. The left-hand shutter is then moved towards the violet end of the spectrum, the right-hand shutter being placed at the position previously occupied by the left-hand shutter. In this way the whole of the spectrum is traversed until the termination of the violet end of the spectrum is finally ascertained with the right-hand shutter. The variation of the size of the patches and the terminations of the spectrum with different intensities of light can be noted. The instrument can also be used for ascertaining the exact position and size of the neutral patch in dichromics, the position of greatest luminosity, and the size and extent of pure colours. When it is used to test colour-blindness the examinee should first be shown some portion of the interior of the spectrum, and then asked to name the various colours which he sees. In this way he will have no clue to the colours which are being shown him.

*Objections to other tests for colour blindness.*—The tests which have been proposed for colour blindness are very numerous, but some are so defective that it is rare to detect a single colour-blind person with them. I have, for instance, tested men whom I knew to be colour blind with certain lanterns, with the result that not a single one was detected. In these so-called tests all the requirements of a test and facts of colour blindness have been neglected. I must, however, refer to three tests constructed by exceptionally able men, each with considerable knowledge of the subject. I refer to the tests of Professor Holmgren, Professor Stilling, and Professor Nagel.

All these tests can be passed at the first attempt without coaching by certain dangerously colour-blind persons, chiefly varieties not known to the inventors, but the chief defect of each is that it is very easy to coach a colour blind person to pass it. The surgeon to one of our largest railway companies told me that when they used Holmgren's test they rejected one man in 300, but with my lantern 12 in the same number. All these three tests are much better tests when the persons to be examined have not seen them before. A colour-blind man may make only one mistake—say, for instance, as in a case I examined the other day with Nagel's test (last edition), he passes the test perfectly with the exception of one mistake, that of calling a grey on one card green. All he has to do is to look for some distinguishing mark on this card in order to go through the test with the ease and certainty of a normal-sighted person. It is the same with Stilling's letters, he has only to note the letter which he was not able to read and the appearance of the card. A normal-sighted man or woman would readily help him. The confusion of green and grey does not appeal to the average man as a serious defect, especially when he sees his friend go through the rest of the test perfectly. He says to himself, I suppose, he sees a tinge of green in that grey. The same man would rightly regard it as a most iniquitous proceeding to endeavour to coach his friend through a test when he had seen him mistake a red for a green light.

Holmgren's test rejects a large number of normal-sighted persons, as may be seen by the reports of the Board of Trade; about 50 per cent. of those who appeal are found to be normal sighted and to have been rejected wrongly.

THE CONVALESCENT HOMES ASSOCIATION.—This association has just issued a useful list of convalescent and other homes receiving London patients with particulars of the terms of admission and other useful information. The list includes homes for men, women, and children, homes for children only, patients requiring surgical treatment, homes for mothers and infants, homes for gentlewomen, and sanatoriums for consumptive patients, the terms of residence ranging from 3*s.* 6*d.* per week upwards. The association points out that they accept no responsibility with regard to the institutions named, and that inclusion in the list does not necessarily imply recommendation nor exclusion the reverse. The compilation will, however, we think, prove of great utility to medical practitioners when selecting a convalescent home for their patients, especially those of limited means. The book can be obtained at the offices of the association, 32, Sackville-street, London, W., at the price of 6*d.*

# THE PATHOLOGY AND TREATMENT OF INJURIES CAUSED BY ELECTRICITY.[1]

BY SIR THOMAS OLIVER, M.A. DURH., M.D. GLASG., F.R.C.P. LOND.,

PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE.

THE increasing use of electricity is introducing fresh dangers within our midst. As an illuminating agent it stands supreme and for motive power its utility is unquestioned. Electricity is therefore likely to have an extended sphere of application in the future. Its powers of maiming the body and of immediately destroying life are well known. Since 1902, the year in which death by electricity became notifiable to the Home Office, the following are the numbers of fatal cases which have been reported: In 1902, 7; in 1903, 4; in 1904, 6; in 1905, 7; in 1906, 10; in 1907, 11; in 1908, 2; and in 1909, 12. Notwithstanding the precautions which have been taken the number of fatal cases has increased, but this is largely in consequence of more persons being brought into contact with electricity. If we add to the above the many cases in which both minor and severe injuries have been received during recent years we can appreciate the need of having regulations drawn out for the guidance and safety of workmen. It is only because the majority of practical electricians are a well-educated and careful class of workmen that accidents are not more frequent. It is the unskilled labourers who contribute largely to the death roll. Many of the accidents are due to inadvertent contact with exposed parts of highly charged metal not sufficiently insulated or to workmen during alterations touching wires into which the current previously withdrawn has been unexpectedly diverted. Usually it is only a single person who is thus fatally caught in the round of the current, but the danger extends to all who unprotected attempt to succour him. The escape of electrical currents, too, under particular circumstances may become the cause of a catastrophe of an appalling nature. How far the West Stanley explosion of nearly two years ago, in which 166 lives were lost, was the result of an electric spark having fired the coal dust in the mine it is impossible to say. Electricity cannot be trifled with. Experience and experiment alike point the way by which some of the dangers incidental to its use may be averted. The danger depends upon the amount of current passing through the body, the kind of contact, and the insulated position of the individual at the particular time. If he is wearing damp boots, standing on wet soil, and his skin is moist, all of these will aggravate the effects of an electrical shock. The danger is not one of high potentiality of current alone, but of it *plus* the conditions under which the current is received.

Voltage in electrical parlance means pressure or electromotive force. It is difficult to say what voltage is fatal to man. In the United States where the current has been used for the electrocution of criminals not less than 1450 volts has been insisted upon, but in some instances death was not instantaneous. As regards illumination of factories, there is one case on record where a lad on taking hold of a lamp which had been burning badly was killed by a 200 volts alternating current. On the other hand, contact with currents carrying 2000 volts pressure has been made and no serious injury followed. Although opinions are divided as to the comparative dangers of "continuous" and "alternating" currents, it is generally believed that of the two the "alternating" current is the more dangerous. Between 1902 and 1908 there were three fatalities due to continuous currents of 250 volts and lower, whereas during the same period 30 deaths were the consequence of alternating currents. The Board of Trade considers alternating currents to be twice as dangerous as continuous. There is no proof that any one man is more susceptible to electric shock than another. It is, as already stated, rather a question of good or bad contact, dampness of skin, and amount of current entering the body. A dry skin offers greater resistance to the entrance of electrical currents than the same when moist. Where the contact is good and conditions

[1] Part of a clinical lecture delivered in the Royal Victoria Infirmary, Newcastle-upon-Tyne, on Nov. 23rd, 1910.

are favourable there may be great destruction of tissue locally or there may be sudden interruption of nerve connexions which cause immediate death. With milder exposures what happens is that the muscles are thrown into a state of tetanic rigidity so that the individual cannot relax grip of any charged object he has taken hold of, and until the circuit is broken it is dangerous for any other person with unprotected hands to try to rescue him. Effects are only produced when electrical currents enter and leave the body. Any pain experienced may be the result of over-stimulation of sensory nerve endings in the skin, strong cramp-like contraction of muscles, or of the local action at the point of contact of the accumulated products arising from electrolytic decomposition. If the injured person does not lose consciousness fear may cause him to faint, and on the re-establishment of the circulation memory of the harrowing event is apt to retard recovery. The individual either remains nervous for a long time afterwards or he complains of frequent headache and ill-defined pains throughout his body, which are aggravated by disturbed electrical conditions of the atmosphere. Within the last two years I have seen two cases in which severe burning was caused by high pressure currents. One of the patients succumbed to his injuries within seven hours after the accident.

CASE 1.—On Jan. 10th, 1909, a labourer, aged 22 years, was admitted into the Newcastle-upon-Tyne Royal Victoria Infirmary in a state of unconsciousness. His body was in places much burnt. He had been working at an electrical power station, and coming into contact with unprotected metal he had received an electric shock from a current of 20,000 volts. There were several large angry-looking and œdematous burns on the shoulders, abdomen, and limbs, also a deep wound on the back of the head, exposing the occipital bone. He was extremely restless; kept shouting and throwing himself about in bed. I saw him with Dr. E. L. Markham, one of the house surgeons, about two hours after his admission. The pulse was rapid, 150 per minute; the heart's sounds were feeble, the pupils were dilated, and corneal reflexes were present. There was profuse perspiration. Shortly afterwards Cheyne-Stokes respiration developed, and within seven hours after his admission patient died, never having regained consciousness. For permission to make use of these details in this lecture I am indebted to my colleague, Mr. H. B. Angus. The post-mortem examination was made by Dr. George Hall, from whose report I extract the following:—

There are numerous charred burns of various sizes on different parts of the body, one of the most serious being a large wound about 3 inches by 2 over the right side of the occipital bone; the charred skin around this cracks on being bent. There is a large burn extending deeply into the muscles 3 × 3 inches over the right deltoid and surrounded by an inflammatory zone. Forearms and hands are badly burnt—third degree. There are four circular charred burns on the front of the abdomen and numerous burns of a similar character on the thighs and legs. On removal of the calvarium and on dividing the occipital bone it is found that while the charring has not extended right through the bone there are acute inflammatory changes in the diploë immediately underlying the superficial burn. The dura mater and membranes at this particular part are extremely congested. On section of the brain a hæmorrhage of about the size of a walnut is found in the substance of the occipital lobe. It corresponds to the external wound on the scalp; it is a quarter of an inch below the surface of the brain and is surrounded by softened tissue and by numerous petechial hæmorrhages in the white matter. The lateral ventricle and the brain tissues generally are congested. The lungs are congested at the bases. In the pericardial sac there are 1½ ounces of blood-stained serum and on the visceral layer of the pericardium numerous petechial hæmorrhages, especially over the base of the left ventricle. The left auricle and ventricle are distended with clotted blood; the muscle of the right side of the heart seems paler than that of the left; the valves are normal. Kidneys are deeply congested. Liver appears to be normal; spleen is congested and slightly larger than normal. Bladder is full of blood-stained urine which gives an acid reaction, has a specific gravity of 1020, contains albumin such as the presence of blood might account for; it is free from sugar. The duodenum and intestines show nothing abnormal.

Dr. F. W. Mott and Dr. Schuster have been kind enough to make sections of portions of the brain for me and to send me a report upon the same. To Dr. Mott and Dr. Schuster, as well as to the London County Asylums Board, I take this opportunity of expressing my grateful thanks. The report states:—

Hæmorrhages were visible to the naked eye in the sections of the brain. Microscopic examination showed that the hæmorrhages were due to ruptured vessels in the cortex and subjacent white matter (Figs. 1 and 2). The blood contained in the vessels and extravasated into the substance of the cortex showed in places evidence of hæmolysis, for amidst the corpuscles were areas of hæmoglobin like coagulum. The alcohol in which the tissues came was deeply stained with blood. The ganglion cells of the cortex all showed marked chromolytic changes (Fig. 3): not a cell could be seen showing the normal Nissl pattern. Many of the cells showed an intracellular network faintly stained with the basophil dye. In some places, especially where there was a hæmorrhagic extravasation, the cells were stained a uniform dull purple colour by the polychrome eosin stain as if a coagulation necrosis had occurred. The large and small cells of the medulla oblongata showed a marked chromolytic change (Fig. 4); there was an absence or great diminution of the chromo-phyllous substance. I do not think these changes could have been due to the time elapsing between death and the autopsy which was 40 hours, but of this I am not certain.

CASE 2.—A youth, aged 18 years, was admitted into the Royal Victoria Infirmary, under the care of Mr. Angus, on Sept. 22nd, 1908, suffering from burns inflicted by an electric wire. Whilst standing on a concrete floor he had touched a wire carrying 6000 volts alternating current with his right hand and received a severe shock. The palmar aspect of the right hand was deeply charred; the plantar surface of the right toes was deeply charred, and the skin beneath the left toes slightly burnt. The shock was combated with warmth and stimulants and the burns were cleansed and dressed with dry antiseptic gauze. Later on the burnt tissues of the right hand sloughed, exposing the flexor tendons, and by degrees the fingers became contracted into the palm. On Oct. 16th Mr. Angus amputated the terminal phalanges of the first, second, and third fingers of the right hand as these had become gangrenous, and he cleansed the palm. On the 20th a graft covering the palm was taken from the side of the chest after the manner of Tagliacozzi—viz., comprising everything in the skin down to the muscle layer—and sewn on to the hand, leaving, however, the base of the flap attached to the chest. In 17 days the flap was separated entirely from the chest. The graft was successful. Although considerably crippled the hand has been saved. The patient can grip a pencil between his right thumb and forefinger and can draw remarkably well.

Direct exposure to strong electric light may be followed by erythema of the skin accompanied by a sensation of heat and by redness of the part exposed to the rays of the electric arc. The features of electrical burns are extensive local destruction of tissue, an angry and gangrenous appearance of the wounds, and slow attempt at healing. The slowness of healing is to be explained not only by the completeness of tissue destruction but by the inclusion of the nerves in the process and by an ascending neuritis with probably death of portion of the nerves. Although the wounds are mostly on the surface yet internal injuries are in many instances received, for several of the victims suffer from convulsions and loss of consciousness. Frequently it is not until the patient is undressed that the extent of the injuries is realised. The boots, for example, may not exhibit any sign of injury, and yet on removing them the feet are found to be deeply lacerated and the bones exposed. Now and again it happens that a person receives a severe electrical shock and at the time there are no external signs of injury and no symptoms on the part of the nervous system. A few days afterwards signs of gangrene appear in some part of a limb and removal of the affected portion by surgical means has to be adopted; ere a few weeks are allowed to proceed gangrene appears somewhere else on the remainder of the limb. Operation after operation is performed in the hope of saving the patient's life, but the concealed internal injuries are so severe and of such an extensive nature as to baffle the resources of surgery.

When the organs of vision have been injured by an electric spark, the eyelids may become red and swollen, the eyelashes and the eyebrows burnt, or there may be marked hyperæmia of the conjunctiva, and complaint by the patient of the presence of a foreign body in the eye. A few days afterwards this is followed by a muco-purulent secretion, so that superadded to the primary hyperæmia there is an infective conjunctivitis frequently accompanied by a mild iritis. In the retinæ are found certain alterations which Davier speaks of as electrocution of the retina. The retina loses its transparency, a slight cloudiness surrounds both the papilla and the large vessels, and extends for a short distance beyond them. The papilla seems soft and its borders ill defined. The vessels appear to be smaller than normal, a circumstance which differentiates the lesion from specific retinitis. These structural alterations may be present without any diminution of the field of vision, and although they may persist for a time they are not followed, according to Minot, by atrophy of the optic nerve.

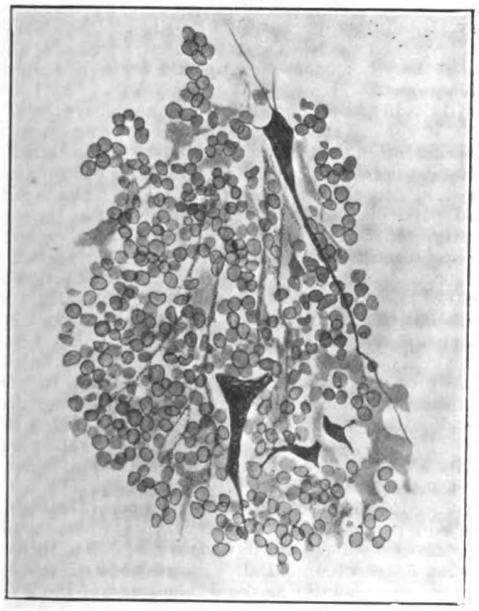
Among the functional eye troubles complained of, mention

may be made of dazzling and of the patient seeing objects coloured red, accompanied by restriction of the visual area. There are an increased watering of the eyes and photophobia, which make it difficult for the patient to gaze long at objects. A few days after the accident neuralgic pains are experienced in the globe of the eye itself or around it, and although the pains are intermittent they are apt to be specially severe at night time and are increased by pressure upon the eyeball and the superficial nerves. The nearer the eye was to the electric flash the greater is the danger to vision. There is always the risk of the trouble assuming the character of hystero-traumatism, where although images are formed perfectly upon the retina, owing to a purely psychical derangement they are not properly perceived. The treatment of electrical injuries of the eyes is difficult. The conjunctivitis is not readily influenced by eye-washes; the neuralgic pains which are stubborn to antipyrin and quinine yield to bromide of potassium.

FIG. 1.

Minute hæmorrhage in brain. In the section hæmoglobin had escaped from the corpuscles. Masses of hæmoglobin could be seen lying between the corpuscles.

FIG. 2.

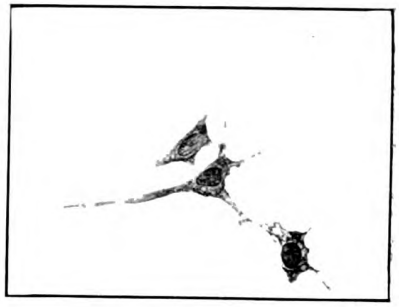


Cells in hæmorrhage. × 640.

What is the cause of death in electrical shock? It was after the Tuileries accident in 1884 that the subject attracted the attention of the medical profession. At that time Grange regarded the medulla oblongata as the part of the brain most sensitive to electrical currents. He had found numerous small hæmorrhages in the bulb which he believed caused death by arresting the action of the heart and respiration through excitation of the vagal centres. D'Arsonval believed death to be the result of stoppage of the heart and respiration.

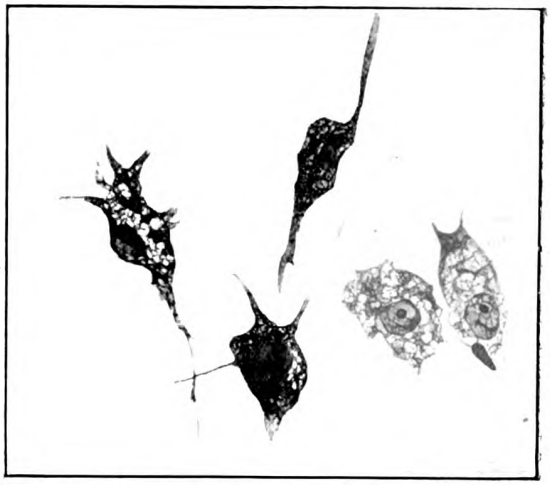
In 1889 Brown and Kennelly in Edison's laboratory carried out several experiments with the view of determining the action of alternating and continuous currents upon dogs and a horse, the voltage for alternating currents varying from 180 to 800. Death followed in from 2 to 65 seconds. With continuous currents the voltages varying from 1000 to 1420 one of the dogs died after ten consecutive shocks. With 700 volts alternating current a horse was killed in 25 seconds.

FIG. 3.



Cells in cortex.

FIG. 4.



Cells from medulla. × 810.

Tatum, experimenting with dogs in 1890, came to the conclusion that death was the result of the action of the electric current upon the heart itself, and that by section of the vagi or the use of atropine the influence of the bulb could be destroyed.

Kratter of Leipzig, writing upon the subject in 1896, lays stress upon the duration of the contact and the kind of animal employed, guinea-pigs and rabbits resisting shock better than dogs. It would seem as if the danger from electric shock increased with the higher development of the central nervous system. With the view of throwing some light upon the subject, in association with Professor Bolam I

performed a series of experiments in 1898.[2] Since in the majority of our experiments the heart was more or less suddenly arrested, while respiration continued, the conclusions we came to were that when death immediately supervenes it is the result of the action of the electric current upon the heart, but whether this organ is paralysed by the current, killed by electrolytic changes, or brought to a standstill by great resistance offered through constriction of the peripheral arteries it is difficult to say.

MM. Prévost and Battelli[3] of Geneva University found that alternating currents of comparatively feeble tension, 20–40 volts, produced fibrillary tremor of the heart; that the heart became paralysed, but that respiration continued; also that with alternating currents, 240–600 volts, respiration and the beat of the heart were immediately arrested; also that high continuous currents were followed by similar effects, but that low voltages did not produce fibrillary tremor.

There are two main theories as to the cause of death in electric shock: (1) inhibition of the medulla oblongata, leading to arrest of respiration, followed by cessation of the beat of the heart; (2) death directly from the heart without the intermediary of respiration. Professor Bolam's and my own experiments rather showed death to be of cardiac origin.

After death from electric shock there is usually found rigidity of the muscles. The heart is flaccid, especially the right ventricle, which contains dark fluid blood. The left ventricle may be empty. The lungs may show nothing abnormal, or there may be signs of congestion if death was not immediate and artificial respiration had been resorted to. The pupils are dilated. The brain and spinal cord may be congested, and the abdominal veins and viscera full of dark blood. There may be hæmorrhage in the brain and petechial hæmorrhages in the pleura and pericardium. Although the blood is usually fluid, it is occasionally coagulated. On spectroscopic examination it is found to contain both oxy-hæmoglobin and reduced hæmoglobin. I have already mentioned the chromolytic changes in the cerebral cells which Dr. Mott found in the portions of brain I submitted to him for microscopical examination.

A lecture on death from electrical shock would be incomplete were no reference made to the electrocution of criminals as carried out in the United States of America. Dr. Léonce Minot[4] has collected cases and summarised them for us. It was in 1889 that the State of New York substituted for hanging death by electrocution. The use of alternating currents was adopted, the voltages varying from 1485 to 2000 and the contact from 10 to 52 seconds. On several occasions a second, third, and even a fourth contact had to be made before pulse and respiration ceased, and even then in one instance three minutes after successive contacts with 1790 volts, and 1900 for eight seconds, and although the current was gradually reduced to 250 volts for 53 seconds there were yet signs of life. Consciousness and respiration were usually abolished after the first contact, but the pulse remained perceptible even when the voltages were higher than 1400. Necropsies of the criminals were made with care. No lesions of a gross character were found which could be regarded as characteristic of death by electricity. At the parts of the body where the electrodes had been applied there were signs of burning. On opening the bodies the blood was found to be dark and fluid, and the organs congested, especially the lungs; there were subpleural and subpericardial ecchymoses; in one instance there were capillary hæmorrhages in the floor of the fourth ventricle. None of these lesions are pathognomonic, since they are found in a certain number of deaths from violent causes, such as hanging, strangulation, and drowning.

*Treatment of the injured.*—For slight shock followed by recovery no treatment is required. For burns the application of boric acid compresses, or charcoal poultices if there is much destruction of tissue, is called for. Where an injured workman is in contact with, or cannot lose grip of, live metal the greatest care must be exercised in touching his body, for any attempt to separate the two might be followed by a disastrous shock to the person rendering assistance. Under any circumstances the breaking of the current means a fresh shock to the individual concerned. The rescuer should have his hands in india-rubber gloves or wrapped round with thick, dry rags. If it is a live wire with which contact has been made this should be cut if possible with long iron scissors in wooden handles. Once the circuit is broken, should there be no signs of life, the body must be placed upon its back and artificial respiration immediately resorted to and continued for a considerable time. Even if there is no quick response, artificial respiration should be continued. In our experiments we succeeded in resuscitating animals whose heart and respiration had ceased for several minutes, and at the Home Office Arbitration Inquiry concerning regulations for electric power-stations one of the witnesses stated that at his works in one man who had received 2000 volts shock the doctor pronounced life to be extinct, but his fellow workmen, to their credit, be it said, immediately resorted to artificial respiration, and as the result of having kept this up for over an hour the man is at work to-day.

# AN EXPERIMENTAL INVESTIGATION INTO THE QUESTION OF THE POSSIBILITY OF MODIFYING THE EFFECT OF AN INOCULATION OF TUBERCULIN BY COMBINING WITH IT A LOCAL ANÆSTHETIC.

BY H. WARREN CROWE, M.D. OXON.

MANY of the recently observed phenomena associated with the exploitation of that form of treatment known as "active immunisation" are extremely difficult of explanation on any hypothesis at present in vogue. It appears that the scope of modern theories of immunity is too confined. Anaphylaxis has produced many ingenious explanations, but none entirely satisfactory. The tuberculin "reaction" is another example; and not less so, that curious effect which follows the repetition of equal small doses of tuberculin in phthisis, allied as it may or may not be to anaphylaxis or to the tuberculin reaction proper.

It will readily be admitted that the nervous system plays the rôle of general supervisor to the various functions which together maintain that fine adjustment to environment which constitutes the fact of "life." In a former communication[1] I suggested that the nervous system might be endowed with a more particular control over certain of the processes of immunity. If such an influence could be demonstrated, then a new and hitherto unexplored field would be opened up for investigation, and, in fact, the present narrow scope of the theories of immunity would be enlarged.

Much patient endeavour must be expended before it could be claimed that such an elusive factor as "nerve control" was definitely proved to have any important bearing on the intimate processes of immunisation. Still, as a first halting step in that direction I venture to submit the investigations herein detailed. The only question upon which I attempt to throw light is whether the inoculation of tuberculin produces its effect in any degree by stimulating afferent nerve endings at the site of injection.

My procedure has been to combine a considerable proportion of a 4 per cent. solution of beta eucaine lactate with varying doses of tuberculin in various cases of phthisis under treatment by vaccines. Daily observations of the opsonic index were recorded during the whole course of the investigation, and as far as possible the blood specimens were taken at the same hour of the day. I must express my gratitude to Dr. Alexander Noble for the invaluable aid he has given me in his untiring efforts to make the indices reliable. It will readily be understood what an advantage there is in having the indices determined by an independent observer.

Table I. shows records of 24 inoculations of tuberculin given in the ordinary way, though seven of these were interspersed amongst doses combined with eucaine, with a view to providing controls.

Table II. consists of similar records where in each case the tuberculin was combined with from 0·3 to 0·5 c.c. of a 4 per cent. solution of eucaine in a ¼ per cent. lysol.

[1] THE LANCET, April 23rd, 1910, p. 1130.

TABLE I.—*T.R., No Eucaine.*

| No. | Dose in thousandths of a mgr. | Initials of patient. | Date. | Opsonic curve.* | Temperature curve.† | Malaise. | Auto-inoculations.‡ | Remarks. |
|---|---|---|---|---|---|---|---|---|
| 1 | 1/100 | M. B. | 12/7/09 | – F. | Rise. | Yes. | No. | Prolonged negative phase. |
| 2 | 1/50 | C. G. | 30/7/09 | F.R.F. | Rise. | Yes. | Yes, 1. | Prolonged negative phase. |

| 10 | 1/10 | ,, | 24/9/10 | R.F.R. | *Nil.* | No. | Yes, 2. | |
| 11 | 1/100 | M. B. | 31/3/10 | F.F. | Rise. | Yes. | No. | Prolonged negative phase. |
| 12 | 1/100 | ,, | 7/4/10 | F.F. | Rise. | Yes. | Yes, 1. | Cf. No. 1 above. Still longer negative phase. |
| 13 | 1/25 | ,, | 7/6/10 | R.F.R. | *Nil.* | No. | No. | Typical tuberculin curve in phthisis as Fig. (A). |
| 14 | 1/15 | ,, | 21/6/10 | R.F.R. | Rise. | Yes. | Yes, 1. | Also this one; cf. Table II., Nos. 4 and 5. |
| 15 | 1/5 | ,, | 18/9/10 | RR.F.R. | Rise. | Yes. | Yes, 1. | Follows after Table II., No. 8, which cf. |
| 16 | 1/25 | E. R. | 14/9/10 | R.F. | *Nil.* | No. | Yes, 1. | This case always had a high temperature, though well and walking; ? nervous. |
| 17 | 1/10 | ,, | 20/9/10 | R.F.R. | *Nil.* | Yes. | Yes. 2. | |
| 18 | 1/50 | M. P. | 30/7/09 | F.R.FR. | Rise. | Yes. | No. | Not typical curves for large prolonged negative and positive phases, were accompanied by marked symptoms. The lesion: old single focus, suddenly aflame. |
| 19 | 1/50 | ,, | 11/8/09 | F.F.R. | Rise. | Yes. | No. | |
| 20 | 1/50 | ,, | 25/8/09 | FFF.R. | *Rise.* | *Yes.* | No. | |
| 21 | 1/100 | R. P. | 16/8/10 | R.F.R. | Rise. | No. | Yes, 1. | Complicated by acute tubercular hip with auto-inoculations going on from that, but not affecting the index as done with human germs as same curves occurred after joint and temperature subsided. Cf. Table I., No. 10. |
| 22 | 1/50 | ,, | 26/8/10 | F.F.R. | F.R. | No. | Yes, 2. | |
| 23 | 1/50 | ,, | 2/9/10 | R.F.RF. | Rise. | No. | Yes, 2. | |
| 24 | 1/10 | ,, | 23/9/10 | R.F.RF. | F.R.F. | No. | Yes, 2. | |

* In this column the first letter indicates whether the index has risen or fallen on the following day. The other letters indicate the subsequent course of the opsonic curve. Thus, for example, No. 18, F.R.FR., shows that the curve begins with a fall, then follows a rise, and a subsequent fall and rise thus: ⋁⋁. A – means no change in the index. If the reader is sufficiently interested in the subject he would find that by drawing diagrammatic representations of the letters under this column he would more easily compare the two tables.

† This column, similarly to the preceding one, indicates the general course of the temperature.

‡ This column takes note of secondary curves, due probably to considerable auto-inoculations, appearing in the course of the primary curve, which result from the tuberculin inoculation.

TABLE II.—*T.R. + Eucaine.*

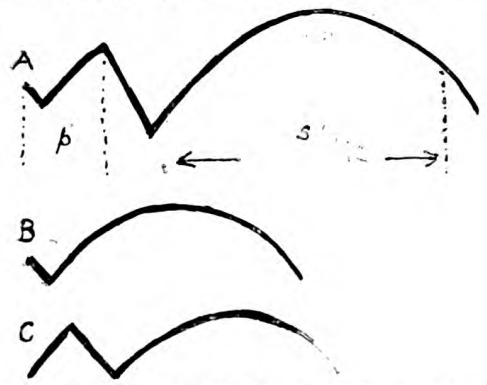
§ I gave the eucaine alone first, then without withdrawing the needle gave the tuberculin. The result was comparable to several of the doses under Table I.

Of the patients referred to in the second table, 2 exhibited temperature charts steadily above normal, 2 showed normal temperatures in the morning, and 1 showed a subnormal temperature throughout. The marginal notes give an indication of the symptoms and conditions which called for comment and also draw attention by cross references to corresponding doses and other comparisons in the two tables.

Before examining the essential points of difference in the two tables it would simplify the business of comparison to describe what seem to be the main characteristics of the opsonic curve as it is seen after an inoculation of tuberculin in phthisis, and to show how it differs from that following tuberculin in a chronic lesion in some other locality. In the paper above referred to an attempt was made to show that the tuberculo-opsonic curve in phthisis was a complex curve which could generally be resolved without difficulty into two or more successive curves, overlapping each other in their incidence; and there it was further suggested that these curves consisted of a primary curve due to the inoculation and one or more secondary curves due to auto-inoculations set up as a result of hyperæmia in the diseased area in the lung. The accompanying figure shows such a curve (A), and for



Primary and secondary inoculation curves: *p*, primary; *s*, secondary.

comparison is shown what may be termed an ideal inoculation curve (B). A third curve (C) is found to occur not infrequently in febrile phthisis. It consists of an appreciable rise lasting for 24 hours or longer, followed by a fall lasting about the same length of time and succeeded by a prolonged positive phase. Wright has described such a preliminary rise as occurring after an inoculation in other conditions, but I understand that he has found it to be of very short duration, being rapidly succeeded by the negative phase. Now this prolonged preliminary rise occurs no less than ten times quite unmistakeably in Table I. (Nos. 5, 8, 9, 10, 13, 14, 16, 21, 23, and 24, and perhaps 7 and 17), whereas in Table II. it occurs only twice (Nos. 9 and 21). Of the two last mentioned the first was undergoing at the time large auto-inoculations with high temperatures, which probably vitiated the curve, and the other has been shown to be possibly uninfluenced by the eucaine.

Look again at the figure (A). Such a curve is found in 16 out of the whole list, when no eucaine was added to the dose, and in 5 of the remainder was obscured or replaced by a quite uncomfortably prolonged negative phase, accompanied by malaise. In Table II. the curve is only found 5 times altogether, and then with diminished distinctness. Compare Table II., No. 10, on Sept 16th, where eucaine was used, with Table I., No. 24, on the 23rd of the same month, where the same dose was given only a week later, but without eucaine. Compare also Table II., Nos. 4 and 5, with Table I., No. 13. Finally, malaise follows 13 of the doses without eucaine and only 2 in Table II., of which one is again the doubtful No. 21.

*Conclusions.*—1. There is a distinct difference in the response to an inoculation of tuberculin in phthisis if eucaine be combined with the dose. 2. The chief proof of this rests on the form of opsonic curve which follows such doses as compared with doses in which no eucaine was given. 3. There is a possibility that an inoculation of tuberculin produces its effect in part by stimulating the central nervous system. 4. Such stimulation may take place at the site of inoculation.

Yelverton, Devon.

# SOME REMARKS ON PANTOPON ANÆSTHESIA.

BY C. LOUIS LEIPOLDT, F.R.C.S. ENG.,

ANÆSTHETIST TO THE GERMAN HOSPITAL, DALSTON; CLINICAL ASSISTANT, VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

DURING the last ten years so many new methods of inducing and maintaining surgical anæsthesia have been placed before the profession that it seems almost supererogatory to add yet another to the number demanding investigation and criticism. But it is fairly obvious that none of the methods now in use can honestly be styled ideal; the very fact that so many novelties are competing for popularity is a proof of the absence of a thoroughly satisfactory anæsthetic. So far as I am aware, up to the present no report of any case in which pantopon has been used as a "combined anæsthetic" has been published in English medical literature, and the conclusions of continental surgeons with regard to this new adjuvant have hitherto received scant attention in this country. As I have now for some time been using the drug a preliminary *résumé* of the results obtained with it may not be without interest to those who are not already acquainted with its possibilities, and it is with that object that these initial notes have been written.

In the early part of 1909 Sahli[1] of Berne, experimenting with the various alkaloids contained in crude opium, concluded that the most effective narcotic was a definite, stable solution of these alkaloids, in which the relative strength of the various constituents was definitely known or could be accurately measured. At his request, Schärger of the firm of La Roche prepared such a mixture, which was provisionally styled "pantopon" (from παν all and ὀπος juice). This, briefly, is a mixture of the soluble chlorides of opium in which the relative strengths of the following are claimed to be known: morphine, narcotine, codeine, papaverine, narceine, thebeine, hydrocotarnine, codamine, laudanine, laudanidine, laudanoeine, meconidine, papaveramine, protopine, lanthopine, cryptopine, goscopine, oxynarcodine, xanthaline, and tritopine. It is obtained as an amorphous, yellowish-brown powder, resembling somewhat finely powdered crude opium, easily soluble in water, less easily in alcohol and acetone, and forming a clear, colourless, or slightly brownish solution which is apparently quite stable at the ordinary temperatures, and which is faintly acid in reaction. One gramme of pantopon is estimated as being equivalent to five grammes of 10 per cent. morphine and 18 per cent. opium, but this estimate is probably too low, especially for anæsthetic purposes. The powder and the solutions have been extensively tried in continental clinics as narcotics and anodynes, and are claimed to be superior to other opium compounds and derivatives. Already a large number of reports on the clinical usefulness of the combination have been published, among which the work of Hallervorden,[2] Heimann,[3] Rodari,[4] Gottlieb,[5] Witowski,[6] and Raffalovitch[7] contains much interesting information. For some time the drug has been used as an adjuvant to general anæsthesia, and the results so far obtained, notably by Brustlein,[8] are so eminently satisfactory that the combination deserves wider trial and investigation. It is almost regularly employed at the German Hospital, Dalston, and has proved remarkably useful.

Combined anæsthesia, in which narcotics are used as a preliminary to the administration of the general anæsthetic, has now been so generally tested that we are in a position to draw certain definite conclusions with regard to its advantages and limitations. The combinations are so varied, ranging from the chloral-urethane group to that in which morphia in some form, either alone or combined with hyoscine, is administered, that it is not easy to collate the findings of various observers. The whole question opens up

such an interesting field of possibilities that it is not surprising to find extreme differences of opinion with regard to individual methods. A few points, however, stand out clearly, and it may not be without interest to draw attention to Burgi's[9] recent elaborate series of experiments in which a large number of combinations were tested. These conclusions have not been challenged; on the contrary, more recent work by Italian critics seems to confirm Burgi's work in substance. He found, what was already known clinically, that two narcotics introduced simultaneously or shortly after each other have a much more powerful effect than when a total quantity of one narcotic, equivalent in strength to the combination, is administered. This triple or quadruple increase of action is greatest when the two narcotics have different cell receptors, and a dose of one drug acts much better when it is given in relatively small quantities, with an interval between each administration, than when it is exhibited at once. These conclusions are of some interest as supporting the Burker[10] theory of narcosis and as yielding certain data which seem at variance with the hypotheses of Overton-Meyer and the Verworn school generally. They are supported by Madelung,[11] who, working with small quantities of scopomorphine, found that this combination very powerfully increases the anæsthetic effect of ether, and that it suffices to produce surgical anæsthesia in animals who are allowed to inspire $CO_2$ or a mixture of this gas and oxygen. Neu's[12] more recent work in this direction is equally interesting, for he found that the administration of small doses of scopomorphine materially increased the effect of gas and oxygen. Rocchi's[13] results were similar with regard to atropine-morphine combinations, and as early as 1880 Surmay[14] pointed out that a preliminary dose of chloral enabled the anæsthetist to use a much smaller quantity of ether than in cases in which no adjuvant had been used. Rave[15] in America and Franck[16] of Bordeaux reported similarly with regard to other combinations; and much more recently Wolffsohn[17]—who was the first observer, I believe, to draw attention to the interesting fact that a positive Wassermann reaction is the rule after combined anæsthesia—has laid stress on the important summative effects of small quantities of a narcotic drug, not in themselves sufficient to produce any appreciable degree of narcosis, in influencing the rapidity of action of general anæsthetics. The advantages of dividing the preliminary dose of narcotic have been concisely summed up by Beinaschewitz,[18] whose conclusions on this subject are well worth study.

These findings are valuable when we consider that pantopon appears to be in many respects an ideal narcotic to employ for anæsthetic purposes. In the majority of cases, as Sahli and his co-workers[19] have shown, it is well tolerated, producing none of the unsatisfactory after results that sometimes follow the administration of solutions of morphia. Raffalovitch, in the interesting thesis already alluded to, states that it influences the respiratory centre much less than does morphia, and Grafenberg,[20] in an equally instructive study in which he contrasted it with scopomorphine, comes to the conclusion that it is in every way preferable, since it is more reliable and has no tendency to cause collapse. It is at present used mainly as an injection, 1 c.cm. of a 2 per cent. solution of the drug being injected an hour before the operation, though, as has already been stated, it is much to be preferred that the dose should be subdivided and administered at intervals. The solution can be bought ready prepared in ampoules, each containing the requisite dose, or it can be readily made by dissolving the powder in a mixture of 75 per cent. water and 25 per cent. glycerine, the solution so obtained being quite stable and sterile. At the German Hospital the ampoules are used, and they have so far proved quite satisfactory. The injection causes a slight tingling, similar to the sensation which is experienced after an ordinary hypodermic of morphia; this soon passes off, and the patient feels no further discomfort. The anodyne action of the drug is very striking; the pulse becomes slower and steadier, the respirations are quieter and more regular, and—a matter of considerable importance to the anæsthetist—the patient is quite tranquil and composed when brought in. The difference between pantopon and scopomorphine in this last particular is very marked. Where a patient has received a comparatively small dose of the latter it often happens that his behaviour on the table is the reverse of satisfactory, especially in cases where oxygen is used in combination with ether or chloroform; in sturdy alcoholic adults this negativism, to use a charitable expression, is sometimes very great. With pantopon I have as yet observed no such preliminary excitement, and the period of induction is very much shortened, even when contrasted with the relatively short stage in scopomorphine anæsthesia. In some cases, where two injections of the drug have been given, somnolence is much greater, and Brustlein has been enabled to perform operations on patients in this condition without availing himself of a general anæsthetic at all. For obvious reasons, however, this course is to be deprecated, especially since we lack conclusive evidence with regard to the narcotic strength of the preparation. I have already stated that I consider the morphia equivalent of pantopon is too low, and it must always be remembered that individual idiosyncrasy towards opium derivatives is sometimes very marked and can never be previously estimated. The combination of morphia with narcotine may have something to do in determining the action of the preparation in certain individuals who appear to respond to it much more quickly than others, and in future it may be preferable to use pleistopon, a combination in which the latter alkaloid does not enter. I have as yet had no opportunity of trying this combination myself, and I know of no reported cases in which it has been employed as a preliminary to general anæsthesia.

A considerable experience of scopomorphine anæsthesia, especially in combination with ether and oxygen, has convinced me that Perrier's[21] strictures on this combination are not altogether undeserved. However easy and pleasant in the majority of cases it renders the anæsthetist's task, especially with regard to inducing narcosis, and however much it minimises the dangers of general anæsthesia, its after results are not always so satisfactory as one could wish. In the first place, the relative length of the apnœic periods during the administration of ether and oxygen are greater than where no narcotic has been used as a preliminary, and though it is easy to overcome this tendency towards apnœa by allowing the patient to breathe into the bag and so to obtain a small quantity of $CO_2$, this course has manifest disadvantages, not to speak of dangers. In the majority of patients the breathing under scopomorphine anæsthesia is apt to be shallow when oxygen is used. The result is invariably some congestion at the lung bases, and there is reason to believe that the percentage of post-anæsthetic broncho-pneumonias is higher in cases where this combination has been used than in those in which ether-oxygen-chloroform alone has been employed. At the German Hospital, where the Roth-Dräger is used as a matter of routine, there is a general feeling that this apparatus is occasionally responsible for the lung complications that sometimes ensue. This opinion I confess I do not share, for ordinary anæsthesia maintained by means of the apparatus certainly does not show an increased percentage of post-operative pulmonary complications. At the Graz clinic, where the Roth-Dräger is constantly used, lung complications are relatively infrequent, though the patients are exposed to more adverse atmospheric conditions than is the case at Dalston. My own experience at Graz certainly does not support the supposition that the apparatus is primarily responsible for such complications, though I am aware that there is ground for believing that the inhalation of oxygen itself under high pressure is likely, in some patients at least, to give rise to such complications owing to the apnœa produced during the administration. Dr. St. John, who is at present working at Professor von Hacker's clinic, has very

kindly supplied me with his observations on the subject which coincide with mine, and Dr. Streissler, the chief assistant at the Graz Hospital, writes to me that he has not met with any pulmonary complications that can justifiably be attributed to the apparatus. At Graz no scopomorphine is given, and at Prague, where the Roth-Dräger is also extensively used, the results, without scopomorphine, are equally satisfactory. It is therefore not unreasonable to regard the pulmonary complications which have occurred in my own practice where the Roth-Dräger has been used, as dependent, to some extent at least, upon the action of this combination. The shallow respirations, together with the initial quickened breathing, may legitimately be regarded as predisposing to such complications, and in my opinion both are due to the scopomorphine. The recent work of Henderson and Scarborough [22] on the causes of death under anæsthesia, and of Collingwood and Boswell [23] on the influence of morphia in raising the threshold for $CO_2$ is of great interest in this connexion, but a discussion on the subject would be out of place in this paper.

Further disadvantages of scopomorphine when oxygen is used conjointly with ether or some other anæsthetic are the increased excitement manifested during induction and the prolonged stupor that follows, during which Cheyne-Stokes breathing is sometimes to be observed. The tendency towards post-operative nausea and sickness, which is greater than when no scopomorphine has been used, must be added as another unsatisfactory concomitant. A preliminary dose of scopomorphine does not diminish the tendency to vomit during the administration, and appears to increase the sickness after the operation, especially in operations on the neck and thorax in which prolonged retching seems to be invariably the case. None of these objections—with the possible exception of vomiting—appear to hold with pantopon. The breathing is throughout regular and quiet, never, except when a double dose has been given, shallow; there is no apnœa whatever. I have never yet observed any vomiting during the administration or immediately afterwards, though the patients sometimes retch considerably later on when returned to bed, so that in this respect pantopon does not seem to be much superior to scopomorphine. It is only fair, however, to say that the after course in the great majority of cases of pantopon anæsthesia is excellent, the patients do not vomit, do not complain of pain, and are quiet and comfortable in bed. The initial stage of induction is almost ideal; the patients are absolutely tranquil, and the calming and quietening effect of the drug is much more marked than is the case with scopomorphine. There is no struggling or excitement, the patient breathes deeply and regularly, the pulse is full and slow, there is an absence of all signs of negativism, and once the case is "under" a very small amount of anæsthetic suffices to keep it in a suitably relaxed condition for the surgeon. I have been at some pains to compare the amount of anæsthetic used in pantopon cases and in those in which scopomorphine has been given; Grafenberg [24] using the Wanscher-Grossmann apparatus and employing ether only, found that a much smaller amount of the anæsthetic was sufficient in pantopon cases than in scopomorphine cases. Sick,[25] employing the Roth-Dräger apparatus, averaged with scopomorphine anæsthesia 8–10 c.cm. (men) and 6–8 c.cm. (women) of chloroform, together with 60–100 c.cm. (men) and 60–90 c.cm. (women) ether per hour of anæsthesia. My own results under similar conditions average 8–14 c.cm. chloroform and 60–130 c.cm. ether per hour. Where no oxygen is used a much smaller quantity of anæsthetic suffices. The following details of some early cases of pantopon anæsthesia are interesting for purposes of comparison:—

CASE 1.—Stout, flabby woman, with apical mitral murmur. Operation for umbilical hernia together with total hysterectomy. ½ c.cm. pantopon administered an hour previously to, and another ½ c.cm. just before, operation. Patient calm, breathing regularly, respirations 18; pulse full and steady, 74. Pupils moderately contracted, reacting to all stimuli. Induction period eight minutes; commenced with oxygen, 7 pints per minute, and ether, starting at 0·5 gramme per minute, gradually rising to 1·5 grammes per minute. Conjunctival reflex present throughout operation which lasted an hour and ten minutes. Pupils small, anæsthesia perfect, no vomiting or retching, no mucus. Patient had edentulous jaws and a very large tongue, with loose, flabby, lips, which interfered somewhat with the mask. Pulse an hour after commencement of administration 72; respirations 14 to 16. Total amount of ether used 62 grammes; no chloroform.

CASE 2.—Male, 33 years of age. Nephrotomy. Similar injections of pantopon. Anæsthesia excellent throughout; conjunctival reflex present. Induction time 10 minutes, period 40 minutes; 96 grammes ether.

CASE 3.—Female, 58 years of age. Cholecystectomy. Patient in very poor condition; pulse at commencement of administration 104, dropped to 85 during anæsthesia. Conjunctival reflex abolished at early stage of anæsthesia. Duration 1 hour and 20 minutes; 160 grammes ether.

CASE 4.—Male, aged 15 years. Hernia inguinalis sinistra. Induction period eight minutes; conjunctival reflex present. Anæsthesia completely satisfactory. Ether 40 grammes.

CASE 5.—Female, aged 44 years. Gall-stones. Cholecystectomy. Very much emaciated, feeble woman. Duration of anæsthesia 1 hour and 40 minutes; ether 160 grammes.

In none of these cases was there the slighest difficulty during the induction or administration. There was no retching, no mucus had to be sponged out from the throat, and the patients were completely relaxed, although for the greater part of the operation they only received ether at the rate of 0·5 to 1 gramme per minute with the full quantity of oxygen—7 pints per minute. In a few cases it has been necessary to give chloroform, mainly during the induction, in order to hasten the anæsthesia in strong, vigorous male patients. Lately, however, I have not used chloroform with pantopon, and when it is remembered that it is exceedingly difficult to keep a sturdy patient sufficiently under the anæsthetic (and almost impossible to do so in the case of an alcoholic) with the Roth-Dräger apparatus when ether is given alone and at a less rapid rate than 1·5 grammes per minute, these results are very satisfactory.

I do not know of any contra-indications for the use of the drug. In no case have any bad results followed its use in kidney operations, and, from an anæsthetic point of view, the most successful cases were those in which the patients were deeply jaundiced. I am inclined to think that pantopon predisposes to bleeding, as in some cases there was considerable oozing; this, however, is probably to be ascribed to the stimulating effect on the skin by the iodine sterilisation. Some observers are apparently averse to administering scopomorphine in cases in which valvular disease of the heart is present: I have not found the slightest disadvantage in doing so, and in one case of pantopon anæsthesia where the patient had very well marked mitral regurgitation the anæsthetic was excellently borne. A possible objection to using the drug lies in the fact that it renders the mucous membranes very dry. Patients are usually very thirsty when they wake, though not as a rule constipated. Cutaneous excretion is augmented, and the sweating is sometimes exceedingly profuse, the patient's shirt being almost saturated with moisture in some cases. There is naturally a very strong opinion against administering opium derivatives to children as a preliminary to anæsthesia. This seems to me to be acting over-cautiously; there are undoubtedly cases in children in which a preliminary administration of a small amount of pantopon would be of great usefulness. The Abbott compound (hyoscine-morphine-cactin) has been used with some success in children's cases and I see no reason why pantopon should not be employed as an adjuvant, as I am convinced that its advantages in mitigating the effects of a prolonged operation on a child, as regards shock, are great, and these advantages outweigh the possible, but more or less theoretical, dangers. Wiki [26] has recently shown that children bear morphia injections remarkably well, especially in cases of profound collapse from pain, and it is just in this class of case that it seems advisable to use pantopon on account of its sedative effect.

The ideal combination for pantopon, so far as surgical anæsthesia is concerned, is with gas and oxygen as a general anæsthetic. This method demands a somewhat complicated apparatus, but is undoubtedly to be preferred to any other. For ordinary purposes, however, the usual methods, either open ether or chloroform administered on a Skinner's mask or A.C.E. on a Rendle, will be found thoroughly satisfactory when pantopon has been given in divided doses beforehand.

A word must be said in conclusion with regard to the dangers of the method. No anæsthetic is ideally safe, but it is always well to bear in mind Bilroth's dictum that an anæsthetic, by itself, is never responsible for a death under anæsthesia. The concomitant causes are so various and so manifold that it is difficult, if not

wholly impossible, to estimate their relative importance in producing a fatal result, and where a new method is in question it is always well to be cautious in ascribing dangers to it on theoretical grounds. Scopomorphine has now been so extensively used that it is possible to estimate its relative safety with some degree of accuracy. Faust,[27] Rinne,[28] and Neuber[29] have reported fatalities, and American observers have added to the number, while more recently Schoemaker[30] and Sick[31] have also discussed the question. Neuber, in an elaborate paper, puts the figures as follows: scopomorphine, 1 in 4762; chloroform, 1 in 2060; ether, 1 in 5930. These are fairly reliable figures, as they have been worked out from a very large number of published and unpublished cases, but it is obvious that a large number of cases of so-called deaths under anæsthetics are never reported and are therefore not available for statistical purposes. With regard to the opium combinations, many of the reported cases are not wholly reliable. Schoemaker's case, in which a patient died after an injection of a quarter of a grain of scopomorphine, is one of those. With regard to pantopon, I know of only one fatality, and it is very doubtful if that can be ascribed to the drug, since there was apparently no necropsy. The patient died the day after the operation in coma; the anæsthesia had apparently been normal throughout. It is generally agreed that death in cases of scopomorphine anæsthesia is due to the morphia. The symptoms, which come on a few hours after the operation, are those of opium poisoning—sleep, deepening into stupor, supervening in coma. With pantopon the picture would probably be similar, and the treatment would be on the lines of an ordinary case of morphia intoxication. It is just as well, therefore, to bear in mind that, according to Rigopoulos,[32] atropine is not of much use in such a condition, but that early intravenous injections of a fairly strong solution of potassium permanganate hold out the best chance of saving the patient. During the administration the size of the pupils does not afford much indication of the depth of anæsthesia when pantopon is used; they are usually contracted, reacting faintly to light, but when much oxygen is given they may remain comparatively large with an equally faint reaction; the conjunctival reflex is hardly ever lost with pantopon. The safest guide to the anæsthetist in this as in most other methods remains a careful attention to all details, especially the cutaneous capillary reflex, and the condition of the breathing though the latter may be almost inaudible and imperceptible in some patients during an apnœic period when oxygen is used.

My thanks are due to Dr. E. Michels for allowing me to make use of some of his cases, and to Dr. A. Oberstadt, the house surgeon, and Dr. G. Dorner for information with regard to the after-history.

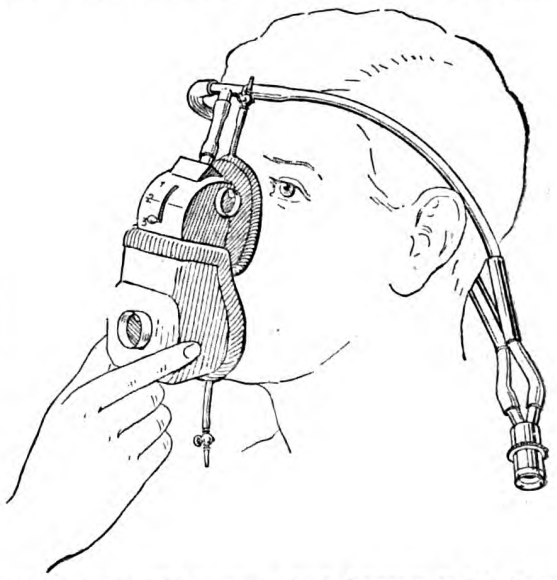
# A NEW METHOD OF ADMINISTERING NITROUS OXIDE, WITH OR WITHOUT OXYGEN, FOR PROLONGED DENTAL OPERATIONS.

BY NORMAN S. HEEGAARD WARNER.

THE apparatus used is shown in the accompanying woodcut, and consists of the following parts.

A special form of inhaler, which I call a *naso-oral inhaler* and which has two separate parts—a nose-piece and a mouth-piece. A metal attachment is adjusted so that two rubber tubes are in connexion with the ordinary "gas bag." These tubes pass one each side of the patient's head, and are joined to a hollow metal T-piece, which rests against the forehead. The vertical or lower part of the T-piece has a wider bore, and is joined to the top of the nose-piece by a short piece of rubber tubing.

*The nose-piece* is so made that it takes up the minimum amount of room (so as not to get in the way of the operator), and at the same time has the maximum width for its apertures. Running down the centre is a sliding plate (the regulator) which can be adjusted to the following positions, so that (1) the supply of gas is immediately cut off and air simultaneously admitted; (2) gas is admitted only to the nose; and (3) gas is admitted to the nose and mouth (as shown in the illustration). In the lower part of the nose-



piece is a rectangular opening, which, however, is not shown in the illustration, as it is covered by the upper part of the mouth-piece, thus indicating Position 3. This opening serves a double purpose: (i.) admits air, *provided that the mouth-piece is removed and the regulator is in Position 1;* (ii.) communicates with the mouth for the passage of gas, *when the mouth-piece is in place and the regulator at Position 3* (*vide* illustration).

An expiratory valve is on either side of the nose-piece. Nose-pieces can be obtained fitted with or without pneumatic rubber cushions, though the former is advised, thus ensuring a better fit round the bridge of the nose Coming off from the smooth facet of metal, just in front of the nitrous oxide tube, but not shown in the woodcut, is a short metal tube for the oxygen attachment. This tube is closed at its upper end by means of a metal cap, to prevent the escape of nitrous oxide when the oxygen attachment is not in use.

*The mouth-piece* needs no special description other than the illustration. It is supplied with an expiratory valve in the centre, and a pneumatic rubber pad or cushion round its sides. The rubber pad is essential in the case of the mouth-piece. Both the rubber pads can be easily removed for sterilisir g purposes.

### I.—*When used for the Administration of Nitrous Oxide without Oxygen.*

The connexions having been made, as already described, the gas-bag filled, and the patient ready with mouth-prop in position, the nose-piece is adjusted with the regulator at 1—i.e., the patient is breathing only air through the nose-piece.

(*a*) *In the case of normal patients.*—A few words of encouragement and instruction should be given the patient as to breathing through the nose. After a few inspirations of air, when he should have become accustomed to the inhaler, and when he is seen to be breathing normally the valves on the stopcock of the gas bag are thrown out of action (as they are unnecessary, there being valves on the nose-piece), and the regulator is then turned to 2. At this point the mouth-piece is put in position, which is, so that its upper border lies between the lowest part of the slot in which the regulator slides, and the upper border of the rectangular opening, which admits air. It is important that a gentle but constant pressure be exerted on the bag, to force the gas through the tubes, otherwise the patient is apt

to strain on inspiring, and hence suffer from feelings of faintness on recovering from the effects of the gas. Also, due to the fact that the pressure of the gas is greater than atmospheric pressure, the inadvertent entrance of air is prevented. If the patient is recovering from the anæsthetic during the operation the pressure should be increased until he is again well under the influence of the gas.

There are several forms of bag compressors on the market, all more or less after the some principle. One that I have found work admirably is the steel-spring compressor that was designed by Mr. J. F. Trewby, house anæsthetist at the Royal Dental Hospital of London, and used by him at that hospital. Another steel compressor—one that is cheaper but equally efficient—is the one designed by Mr. F. Coleman, assistant dental surgeon to the Royal Dental Hospital of London. Thirdly, the gas-bag could be compressed by an assistant; but if one is unobtainable the anæsthetist should use his own arm or hand. The last mentioned can be managed quite well after a little practice.

The most scientific and preferable method, however, is to use a special form of gas regulator, which can be joined to the gas cylinder, and which obviates the necessity of using a gas bag. Connected to both cyclinder and gas regulator are nine coils of thick copper wire, beneath which is a small metal stand, on which rests an ordinary spirit lamp. This little lamp when lighted heats the copper wire, two or three minutes only being necessary to produce gas at body heat, provided an average pressure is exerted. Fixed to the top of this gas regulator is a fine screw adjustment, by means of which *any* desired pressure can be obtained. If this regulator is used the gas bottles will be found not to freeze, as is often the case if a great number of gas patients are treated in immediate sequence.

Usually in from 45 seconds to a minute the mouth-piece can be removed, and the dental operation started. There is no need to "push the anæsthesia" to the end of the third stage, as is done with the ordinary face-piece, but the operation can be proceeded with at the *beginning* of the third stage of nitrous oxide narcosis.

*Best signs indicating the stage in the administration at which to remove mouth-piece.*—(i.) Eyes become dull and expressionless, but sclerotic reflex persists; (ii.) the pupils begin to dilate; (iii.) strabismus sometimes occurs; (iv.) limbs become flaccid. While the dental operation is proceeding, anæsthesia is kept up, until the breathing loses its rhythm and a slight stertor is audible, together with other approaching signs of deep nitrous oxide anæsthesia. These signs generally occur within 30 seconds of the removal of the mouth-piece, and at this point two full inspirations of air should be allowed, or the patient should be permitted to breathe air for about five seconds. When these deeper signs again appear the patient can have, as a rule, from 5 to 20 seconds for breathing air—i.e., from two to eight inspirations—when the gas should again be turned on by the regulator on nose-piece.

The administrator should endeavour to steer clear of deeper nitrous oxide narcosis, and should avoid such signs of deep anæsthesia as "oscillation of the eyeballs," and "jactitations" (clonic muscular movements of the thoracic and abdominal muscles and extremities, and spasmodic elevations of the larynx towards the epiglottis and base of the tongue, the last mentioned giving rise to the stertor).

I find it better to begin the administration of gas through the nose only, as it is easier for the patient to continue breathing so, after the removal of the mouth-piece. The mouth-piece could be discarded in normal cases, the patient's mouth being closed at the beginning of the administration, which is conducted by means of the nose-piece alone. When the patient is sufficiently under his mouth could be opened up with a Mason's gag.

(*b*) *In the case of alcoholic patients and mouth-breathers, &c.*—The administration is proceeded with on similar lines as before, with the exception that when the patient has inspired one or two breaths of air through the nose-piece, and has become used to the inhaler, the mouth-piece is adjusted *immediately*, and the regulator moved to Position 3 (as depicted in the illustration)—i.e., the inhaler is practically converted into an ordinary face-piece. The patient is now having gas administered to him through the nose and mouth. This is kept up until the patient is ready for the operation, when the regulator is moved to Position 2, and the mouth-piece withdrawn. This method is desirable with powerful men, or alcoholic and other excitable patients, as the period of induction is considerably lessened. Mouth-breathers are certainly not very good patients as regards nasal administration, but even they can be made to have a longer period of anæsthesia than they would have with the ordinary face-piece method.

### II.—*When used for the Administration of Nitrous Oxide with Oxygen.*

As already explained, there is a short metal tube of narrow bore at top of nose-piece as a fixture, to which another tube of similar bore can be adjusted. This latter tube is the oxygen attachment, and has fixed to it an ordinary long-arm tap for regulating the supply of oxygen. This tap can be made to pass across an arc plate, which has a series of depressions into which a stud spring catches. The depressions are placed very close together, so as to give the smallest variation to the arm, at the same time holding it securely during any of the movements (Weiss). When the arm, or tap, is vertical it is full on, and when horizontal the oxygen is turned off.

A rubber tube of equal bore is joined to the other end of this metal tube, and communicates with the oxygen bag, which should have a capacity of about one and a half gallons. The nitrous oxide and oxygen bags are both filled and hung on a stand or on to a metal bar, which can be adjusted to any operating chair. The bags should hang immediately to the left of patient (out of the operator's way), and in such a position that they can easily be seen by the anæsthetist. They should also be as near to the patient's head as possible, so that the minimum distance from gas bags to nose-piece can be obtained.

If a pressure regulator for the $N_2O$ is used, only one bag with a spring compressor will be needed—viz, that for the oxygen. The $N_2O$ and the oxygen must, of course, be administered under an equal pressure.

*The oxygen is used simply to control the number of respirations, and keep down the cyanosis.*

Usually in about 45 seconds the breathing becomes slightly laboured and noisy. At this point oxygen is gradually admitted, when the breathing will generally quieten down. If excitement ensues, the supply of oxygen is lessened or turned off altogether, and two or three inspirations of nitrous oxide allowed. After this the oxygen can be turned on again very gradually. *In this manner the respirations can be controlled.* Air, however, should be admitted from time to time.

*Signs to watch for* to indicate the best time for removal of mouth-piece: (i.) *Respiration* is regular and tranquil, or is softly snoring in character (similar to the breathing in a good chloroform anæsthesia); (ii.) the sclerotic or corneal reflex is abolished; (iii.) *the eyeballs* are fixed and widely staring, or present slight oscillatory movements; (iv.) *extremities* are flaccid (or, in rare cases, very rigid). Sometimes the corneal reflex is still present, when the other signs appear, in which case the mouth-piece can safely be withdrawn and the operation started. The other particulars are essentially the same as in the administration of nitrous oxide alone. This method should be used in cases of disease in the circulatory system, heart weakness, &c.

### *Advantages of the Method.*

I. *Its advantage over the usual method of administering nitrous oxide and oxygen, or nitrous oxide alone.*—1. A much longer anæsthesia is obtained. Mr. J. H. Patterson, by means of the nasal method of administration, maintained anæsthesia for 9 minutes 55 seconds, using nitrous oxide without oxygen. This was at a public demonstration at Cambridge on a man aged 35 years. The patient was kept absolutely quiet, and recovered after a very few minutes. During anæsthesia two exposed and inflamed pulps were removed, and the two teeth partly prepared for crowning. In addition to this 18 teeth were extracted. On 23 occasions the anæsthesia has exceeded four minutes, but it must be mentioned that these times represent the actual duration of the operation and *not the total available anæsthesia*, which would be 20 or 30 seconds longer, and which *could have been further prolonged had the operation required it*.

2. There is no necessity to "push the anæsthetic" at all, as is often done to an asphyxial point in the ordinary face-piece method, in order to maintain a longer anæsthesia. Many hold the view that this "pushing the gas to the utmost limit" is unscientific and wrong in principle, though

one need not doubt for a minute that it is perfectly safe in the hands of an expert anæsthetist.

3. *The operator* would appreciate this method, as it gives him longer time to do the work in hand thoroughly. Each extraction being performed deliberately, would be a great advantage to—

4. *The patient*, inasmuch that it would mean less damage to the alveolar process, and thus a quicker healing and absorption of the tooth sockets.

5. The instantaneous action of the oxygen in arresting accelerated breathing.

II. *Its advantage over ether, ethyl chloride, and chloroform.*—1. It is a safer anæsthetic. 2. It requires no special preparation of the patient. 3. The patient's recovery is much quicker, and is, as a rule, unattended by any unpleasant after-effects, as vomiting, headache, &c., the patient being quite able to go home after a few minutes.

*Advantages of the Apparatus.*

1. The extreme simplicity and ease in learning how to manage it. The anæsthetist practically has the whole control of the inhaler and the patient, in the small handle of the regulator.

2. Only one hand is necessary to hold the entire inhaler in position (i.e., both nose-piece and mouth-piece together), *leaving the other hand free* to manipulate the gag, &c.

3. The *same* movement of the regulator cuts the "gas" off and *simultaneously* admits air, *which enters immediately below the patient's nostrils.*

4. There is no need to remove the nose-piece from the patient's face to admit air, this being a great advantage to the operator. Its shape, also, is such that it is well out of the operator's way.

5. The Naso-Oral Inhaler will fit practically everybody.

6. The nose-piece is so made that it takes up the minimum amount of space, and at the same time has the maximum size for its apertures.

7. The oxygen is quite independent of the $N_2O$.

8. The quantity of oxygen used is always visible.

9. Great economy of oxygen.

10. Great economy of $N_2O$ if a regulator is used.

11. Definite proportions of air, $N_2O$, and oxygen can be admitted, if required, by decreasing the pressure of the $N_2O$ and the oxygen, and moving the regulator on the nose-piece to any desired point *between* positions 1 and 2.

12. Both nose-piece and mouth-piece are supplied with expiratory valves.

13. The apparatus can easily be adjusted to any gas-bag, gasometer, regulator, or stop-cock that the dental surgeon may already have in his possession.

This apparatus has had a successful trial at Guy's Hospital Dental Out-patient Department during the summer term and long vacation, and has been approved by the dental surgeons and anæsthetists present.

The following can be cited as examples of two of the cases, which we had during the winter session :—

CASE 1.—One Saturday morning (Oct. 22nd, 1910) Mr. Marmaduke Page easily maintained anæsthesia with this apparatus for a period of about seven or eight minutes, though, unfortunately, no exact time was recorded. During anæsthesia, Mr. Montagu Hopson removed a myeloid epulis from an upper jaw, and at the same time extracted the adjoining right central incisor. Both sides of the alveolar process were thoroughly scraped and then cauterised with pure carbolic acid. After this, the incisor was replanted, being kept in place by a special dental splint made of metal, which was cemented over the teeth with copper oxy-phosphate. The splint was held firmly in position while the cement set, anæsthesia being maintained during the whole process. The patient, a girl, aged 13 years, had a quick recovery, with *no* unpleasant after-effects, and was able to walk home almost immediately.

CASE 2.—A similar operation took place on Saturday, Nov. 19th, 1910, when Mr. Montagu Hopson again removed a myeloid sarcoma, with extraction and replantation of the adjoining lateral incisor. In this case anæsthesia was maintained for *10 minutes 25 seconds*—i.e., until the completion of the operation. A longer anæsthesia was required on this occasion, owing to the fact that the dental pulp was removed and the nerve canal carefully filled with an antiseptic material prior to the replantation of the incisor. A special dental splint was then applied as before. The patient (female, aged 22 years) had a similar recovery as that mentioned in Case 1, which was excellent in every way. It should be remarked that she was distinctly a very neurotic patient, and a pronounced mouth-breather. The third position of the regulator on the nose-piece proved of great value.

I should like to acknowledge that the appearance of this apparatus is largely due to the excellent instruction and practice that I was fortunate enough in obtaining from the staff anæsthetist who taught me. If, by chance, he should read this article he will see that I fully appreciate the 12 months' course of instruction that he gave me, and the splendid practice I had in administering general anæsthetics as his "full clerk" in the surgical and dental out-patient department.

I am grateful also to the dental surgeons, assistant dental surgeons, and anæsthetists, for their courtesy and kindness in allowing me to use the inhaler in the out-patient department at Guy's Hospital.

Acknowledgments are due to the Dental Manufacturing Company, of Newman-street, Oxford-street, W., for their willingness in making the apparatus for me, for their help in assisting me in getting out a universal shaped nose-piece, and for their patience in making many slight alterations to perfect the same.

In conclusion, I wish to thank Mr. Kenneth Hoby, L.D.S. Eng., and Mr. Ellison, co-manager of the company, for help as regards the drawings and woodcut.

# Clinical Notes:

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### THE ADMINISTRATION OF THYROID GLAND SUBSTANCE UPON SERUM RASH AND SERUM SICKNESS IN DIPHTHERIA.

BY A. E. HODGSON, M.B. EDIN., D.P.H. CAMB.,
RESIDENT MEDICAL OFFICER, CITY HOSPITAL EAST, LIVERPOOL.

THE occurrence of serum rashes, either alone or in conjunction with high temperature, arthritic pains, œdema, inflamed throat, adenitis, rhinitis, albuminuria, &c., forming the syndrome designated by von Pirquet as "serum disease," after the hypodermic injection of diphtheria antitoxin and other sera, and the graver anaphylactic complications, have attracted very considerable attention during recent years, both at home and abroad.

The conclusions most generally accepted are: (1) That the phenomena are not due to any substance in the antitoxic elements of the serum, but to a protein body inherent in the serum itself; (2) that serum rash and serum sickness or disease may follow one injection only, but will follow more rapidly when a second injection is made, coming on earlier as a rule, the more recent the first injection; and (3) that anaphylaxis usually only becomes a possibility when a second injection is made from 10 to 12 days and onwards, after the primary one.

Simple serum rash may be of no consequence in a case of diphtheria, in so far as bad results are concerned. On not a few occasions however, I have seen infants rendered distinctly "croupy" by œdema of portions of the air passages, coincident with, or resultant upon, an urticarial serum rash. Serum sickness, when severe, may very considerably tax a patient whose system is already burdened with the toxins of diphtheria; and I cannot agree with a recent writer in whose opinion the occurrence of a sharp febrile reaction has been rather useful than otherwise in very prostrate patients. The pyrexia, amounting to 103° F., or even 104° in some cases which I have observed, cannot but have some detrimental effect upon the cardiac muscle. Similarly, the sudden œdemas are commonly accompanied by an alarming fall in blood tension. Two cases in my recollection—each suffering from only a comparatively mild attack of diphtheria—came to a fatal issue as a result of exhaustion following a severe attack of serum sickness. The condition of anaphylaxis, I have fortunately not encountered as yet.

The conclusions referred to earlier undoubtedly include certain main factors involved in the causation of these conditions; but that other elements enter into the etiology is also admissible. Clinical experience proves that one particular series or batch of serum (probably from a particular horse), will cause a higher percentage of undesirable sequelæ than another series; and may there not be other factors inherent in, or peculiar to, the patient himself?

In a paper entitled, "Serum Sickness and Sudden Death following the Hypodermic Administration of Antitoxin," by Dr. Miller and Dr. Root of Detroit, published in the *Therapeutic Gazette* for February, 1910, the writers discuss this point, and in their conclusions suggest the possibility of a relationship between serum sickness and sudden death and "status lymphaticus or some allied condition"; or, in other words, that these particular antitoxin sequelæ may bear some connexion with a greater or less degree of a "hyper-lymphatic" state, if I may coin such an expression.

Following up this idea, with particular regard to serum sickness, and with a view of counteracting any tendency to this hyper-lymphatic or hyper-thymic state, a number of cases of diphtheria were given thyroid gland substance in the form of thyroid gland tablets (Parke, Davis, and Co.), simultaneously with, and for some days following, the administration of antitoxin. The dosage employed was, roughly, as follows: Up to 5 years, 1¼ grains daily, for six doses (decreased in infants); from 5 to 10 years, 2½ grains daily, for six doses; from 10 to 15 years and upwards, 5 grains on alternate days, for four doses. In all, 100 cases were observed, 50 receiving thyroid and 50 receiving none, the latter acting as control cases. The antitoxin employed was, in all cases, taken from a serum series which was clinically known to produce a large incidence of rashes, &c. My results may be tabulated thus:—

| | Cases receiving thyroid. | Cases not receiving thyroid. |
|---|---|---|
| Total number observed ... ... ... | 50 | 50 |
| No sequelæ ... ... ... ... ... ... | 29 | 22 |
| Simple rash ... ... ... ... ... ... | 15 | 12 |
| Serum sickness ... ... ... ... ... | 6 | 16 |

The figures of the first and second sections are not particularly striking, but the large number of cases in the non-thyroid column which suffered from serum sickness, and the small number in the thyroid column, at least suggest that the thyroid gland substance has some effect in modifying the condition.

The number of cases under observation, however, is not sufficiently large to admit of the drawing of anything in the shape of a definite conclusion; nevertheless, the results may be of sufficient interest to stimulate further observations in this subject.

Liverpool.

## AUTO-INOCULATION AND MASSAGE IN A CASE OF GONORRHŒAL SYNOVITIS.

BY J. R. RIGDEN TRIST, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient in this case, a man, aged 26 years, was under my care four years ago suffering from gonorrhœa. There was considerable fever, and for a fortnight he was very ill; there was also a severe conjunctivitis. He was kept in bed and thorough irrigation with argyrol was followed by complete recovery of the eyes. The urethra having been washed out with argyrol, he began to improve, and by the end of a month was fairly happy and comfortable and taking his food well, and the temperature had begun to settle. He then had pain in his right knee and the temperature went up to over 100° F. There was a gonorrhœal synovitis. Immobilisation and fomentation of the affected knee with continuance of active measures to the urethra were followed by a commencing fall of temperature in about a week, and at the end of a fortnight I ordered massage *once* to the affected joint, taking care that the temperature was observed. Within 12 hours the temperature was over 100°. I interpreted this as evidence that the massage had produced a condition of auto-inoculation. I waited for the temperature to settle down again, as it did in less than a week, and repeated the massage; a similar but less pronounced reaction ensued. The treatment was repeated, the temperature chart being used as a guide, and it was found that longer massage was needed before the reaction was observed. Massage was continued periodically on this plan until no reaction took place, and the patient left the nursing home apparently cured at the end of about eight weeks.

I should not, I think, adopt this method again in the treatment of gonorrhœa because I should use a gonococcus vaccine, but I have thought that the case is instructive as bearing on the subject of auto-inoculation so ably dealt with in Dr. Clive Rivière's thoughtful paper in THE LANCET of Jan. 28th.

Auto-inoculation is, I take it, an important factor in the good results obtained by massage in acute osteo-arthritis, a condition in which the preparation of a vaccine is not always possible owing to the difficulty of determining the organism or organisms responsible for the lesions.

## ROYAL SOCIETY OF MEDICINE.

### SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

*Exhibition of Cases and Specimens.—Splenomegaly.—Ulcerative Stomatitis in Children.*

A MEETING of this section was held on Jan. 27th, Dr. E. CAUTLEY, the President, being in the chair.

Dr. ERIC PRITCHARD showed: 1. Intermittent Word-blindness (Congenital) in a boy, aged 8½ years, who was both intelligent and dexterous. His vision was normal and his hearing good. He was slow at learning to read, but quick at mental arithmetic, and had no difficulty in reading Arabic numerals. He could recognise simple words when spelt aloud, but as a rule was quite unable to recognise the same words when written. On occasions, however, he could read simple sentences. He could write from dictation and copy written words, but did not understand their meaning unless he repeated the letters slowly, or slowly performed the movements for writing them. Thus, though his visual memories for words and letters were defective, his auditory and kinæsthetic memories were good. The intermittent character of the word-blindness was suggestive that the condition was a psychosis rather than due to a defect in the visual word centre. 2. Idioglossia in a girl, aged 9½ years. The child was prematurely born, and her mother's half brother was a deaf-mute. She was two years old before her speech was intelligible. She was a bright child, who wrote and composed well. Her mental condition was normal, but her hearing was slightly defective. The vowel sounds were more or less correctly pronounced, but consonants presented a difficulty, C, D, T, G being all pronounced Nee, H as Hay, J as Nai, S and X as Ai, V as Mew, Z as Ney, &c.

Mr. H. S. CLOGG exhibited a specimen from the case of Necrosis of the Lower Jaw, shown at the last meeting. The child subsequently had abscesses on either side of the jaw, which were incised, and it was determined to remove the necrosed portion of the bone. The specimen consisted of the whole of the lower jaw except the inner shell of the ascending ramus and the condyloid process on the left side. In the place of the jaw the child now had a firm, solid arch, but whether this was bone or not it was impossible to say.

Dr. T. R. C. WHIPHAM showed a case of Enlargement of the Liver in a healthy-looking boy, aged 9 years, with no symptoms except slight jaundice. The liver was enormous, reaching down to the anterior superior spine of the ilium and to the umbilicus in the middle line and extending below the left costal margin. In the epigastric angle was a large round swelling, which appeared to rise from the surface of the liver and was more elastic than the rest of the organ. The spleen at one time had been just palpable below the ribs. There was no ascites and the chest was normal. There was no enlargement of glands anywhere. The blood showed an eosinophilia of 7·8 per cent. but no other marked changes. The boy presented no external signs of congenital syphilis, but there was a history of the mother having had three miscarriages. During the past five weeks no change had

occurred in the patient's condition and his temperature had been normal. The general opinion was that the case was one of hydatid cyst, but diagnoses of gumma and hypernephroma were also suggested.

Mr. S. STEPHENSON showed a case of Embolism of the Central Artery of the Retina in a girl, aged 11¾ years, with no signs of inherited syphilis. The patient had mitral regurgitation, but presented no evidence of mitral stenosis. On Dec. 8th she had slight pain over the left eye, and the next morning found that the sight had done. On examination there was no perception of light in the eye. The retinal arteries were filiform and the yellow spot region was œdematous, with a red spot at the fovea. The disc was blurred by the surrounding œdema. The disc had gradually become atrophic and the œdema had practically disappeared, so that the contrast between the fovea and the surrounding fundus was not pronounced. The arteries were still smaller than normal. When shown the eye had sufficient sight to distinguish between light and dark.

Dr. K. KELLIE showed: 1. Two cases of Infantilism. (*a*) A girl, aged 4 years; weight 17 lb. 2 oz.; height 29½ inches. The abdomen was large and suggested at first tuberculous peritonitis, but injection of tuberculin and von Pirquet's test were negative. The stools were large and greasy, showing that probably the pancreas was at fault. (*b*) A twin boy, aged 3¼ years; weight 16 lb; height 28 inches. The patient could not walk and could only speak a few words. The stools were frequent, foul, and slimy. 2. Persistent Jaundice in a male infant, aged 5 months. Jaundice had been noticed since the fourth day and had varied slightly in intensity. The motions were colourless. The liver was enlarged to three fingers' breadth below the costal margin. There was no history of syphilis. The diagnosis lay between congenital syphilis and congenital obliteration of the bile ducts.

Dr. F PARKES WEBER read a paper on Splenomegaly with Recurrent Jaundice ending in Hepatic Cirrhosis and Ascites, with remarks on the Splenomegaly of Inherited Syphilis in Children. Various cases were described or referred to. From a study of his own and other cases, and from the literature of the subject Dr. Weber came to the following conclusions: 1. Moderate splenomegaly in children about the ages of 5 to 16 years may be almost the only evidence of an inherited syphilitic taint, and is often accompanied by occasional (usually only slight) attacks of obstructive jaundice. 2. Hepatic cirrhosis, with or without ascites, may be associated with splenomegaly, and at the time of death is probably usually of the ordinary "hob-nail" type. 3. Though it seems doubtful that the cirrhosis of the liver in these cases is of specific syphilitic origin, it is quite possible that the presence of an inherited syphilitic taint may diminish the resistance of the liver towards the action of toxins (including alcohol) and render it specially liable to cirrhosis. 4. The inherited syphilis in such cases need not necessarily be associated with retardation in general physical development. 5. Great caution must be employed with regard to anti-syphilitic, especially mercurial, treatment, probably on account of the general delicacy of the patients and their liability to renal and catarrhal complications. 6. There may be very little real anæmia or none at all. There may even be more or less polycythæmia, probably of "reactive" nature. 7. Abdominal crises (pain, &c.) may occasionally occur. 8. Some cases of familial splenomegaly in two or more brothers and sisters may perhaps be dependent on inherited syphilis. 9. Splenomegaly in children may be the most important sign of the presence of hepatic cirrhosis. 10. Some cases of splenomegaly in children with inherited syphilis probably ultimately present the characteristic clinical features of splenic anæmia or Banti's disease.

Mr. S. F. ROSE read a paper on Ulcerative Stomatitis in Children, laying stress on the typical distribution of the lesion on one side of the mouth and the efficacy of potassium chlorate as a means of treatment. The disease occurred for the most part in ill-nourished and neglected children, and was frequently started by one or more loose or septic teeth.

The cases and papers were discussed by the PRESIDENT, Dr. G. DE B. TURTLE, Mr. W. MILNER BURGESS, Dr. J. PORTER PARKINSON, Dr. J. W. CARR, Dr. G. A. SUTHERLAND, Dr. PRITCHARD, Dr. J. D. ROLLESTON, Dr. F. LANGMEAD, Mr. S. STEPHENSON, and Dr. PARKES WEBER.

## SECTION OF BALNEOLOGY AND CLIMATOLOGY.

*Osteo-arthritis and its Relation to Chronic Rheumatism.*

A MEETING of this section was held on Jan. 27th, Dr. T. F. GARDNER, President of the section, being in the chair.

Dr. C. W. BUCKLEY (Buxton) read a paper entitled "Osteo-arthritis and its Relation to Chronic Rheumatism," which was followed by a discussion. He said:—Osteo-arthritis is generally assumed to be a form of arthritis characterised by bony changes in connexion with the joints. Bony changes occur in many diverse forms of arthritis, such as pyæmic tuberculosis, gonorrhœal and gouty arthritis, and in the arthropathies, as well as in those conditions to which the name is more definitely applied, but in many cases of so-called osteo-arthritis the stage of bony change is never reached. Bony changes of hypertrophic type are essentially secondary and reparative and do not characterise any particular disease. The cases in which there is no other symptom than stiffness and creaking of the knee-joints are commonly a chronic synovitis due to wear and tear plus increased vulnerability of the joints from heredity or modified vascular supply, such as may be caused by varicose veins, and are then best described as chronic villous arthritis; but slight bony changes may occur in the form of osteophytes arising from the patella. This links them to certain other forms of osteo-arthritis, in which no specific cause is discoverable and which have been termed hypertrophic arthritis. In order to differentiate these two conditions from gouty and other forms of arthritis there is much to be said in favour of the term chronic articular rheumatism, which in spite of possible confusion with rheumatic fever would more clearly indicate their pathology and treatment, and the name osteo-arthritis should be abandoned altogether.

Dr. J. B BURT (Buxton) said that when they considered osteo-arthritis in such a condition as Heberden's nodes, they found that the formation of osteophytes was merely a compensation change. It seemed unreasonable to classify a group of clinical diseases under the term osteo-arthritis if that were only a secondary condition.

Dr. F. A. DE T. MOUILLOT (Harrogate) believed that the differential diagnosis of the different forms of arthritis was of great practical importance, as many patients' lives were made miserable by a diagnosis of rheumatoid arthritis on very insufficient evidence, sometimes the only symptom being a creaking of the knees. He also related a few cases showing how one form of arthritic disease was added to one already existing, such as gout, or rheumatic fever, or rheumatoid arthritis.

Dr. LEONARD WILLIAMS said that it was probable that the joints were if not excretory organs, then elaborating organs, enabling some materials to be more easily excreted. From the sex incidence of such diseases as gout and rheumatoid arthritis it was reasonable to suppose that the organs peculiar to the sexes, the testicle and the ovary, and the internal secretions were primarily responsible for the diseases in question.

Dr. ERNEST YOUNG suggested that members of the section should make careful clinical notes of these cases for the next two years. The collective evidence which might thus be obtained would form a far more satisfactory basis for classification than that which existed at the present time.

Dr. BUCKLEY, in reply, referred to the difficulty in diagnosis, and considered that rheumatoid arthritis was more frequently met with in young women and the conditions known as osteo-arthritis at the menopause. He welcomed the suggestion that members should make a careful study of a series of cases with a view to a future discussion which might greatly assist in the differentiation of these disorders.

## NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

*Non-malignant Diseases of the Breast and their Relation to Mammary Cancer.*

A JOINT meeting of this society and the Nottingham Division of the British Medical Association was held on Feb. 1st, Mr. W. MORLEY WILLIS being in the chair.

Mr. W. SAMPSON HANDLEY, in an address on Non-malignant Diseases of the Breast and their Relation to

has omitted any colours as carefully as if mistakes had been made. He should ask the candidate to match one of the omitted colours.

The examiner will soon find out from experience those colours which are named and matched wrongly by colour-blind persons; he should ask the examinee to name some of these colours.

Any candidate should be rejected who calls an orange or red, green or brown; black, red, or *vice versâ*; or green, either purple, rose, red, grey, brown, or violet. Similar mistakes in matching necessitate objection. A candidate who puts purple, rose, or blue with violet, or yellow-brown with orange is most probably dangerously colour blind and should be very carefully examined. There are cases which pass the Holmgren test with ease that fail in the most conclusive manner with my classification test. They put green with orange, brown and black with red, and grey with blue-green. This is due to a different selection both of test colours and confusion colours. Orange is by far the most important test colour and its confusion with green by the dichromics is very conclusive. The three other test colours —violet, red, and blue-green—represent both ends of the spectrum and the neutral point in dichromic cases, and practically these colours are those with which most mistakes are made. This test can only be regarded as supplementary to the lantern test.

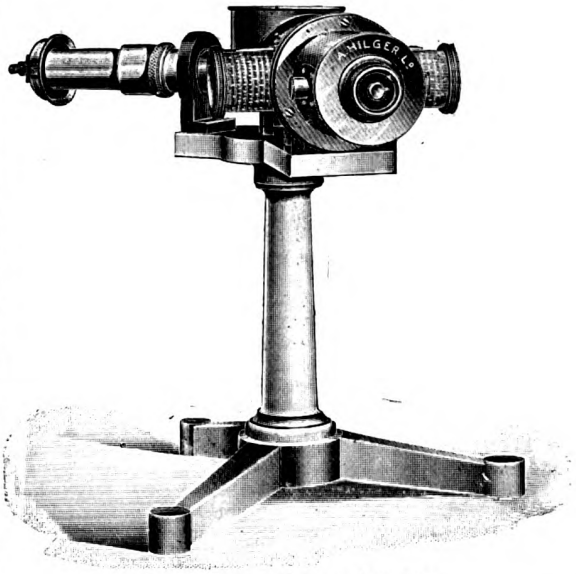
2. *The pocket test.*—This consists of 19 cards on 9 of which are 112 single threads of wool and 14 pieces of twisted silk similar to those in the Classification Test. These are numbered consecutively, with the exception of the first thread of the first four cards and the last thread of the next four cards. The end threads of the first four cards I. to IV. form the tests; they are orange, violet, red, and blue-green. There are also cards on which red, orange, green, blue, violet and purple, and grey respectively are to be found. There are also two special cards marked "Without Red" and two special cards marked "Without Green."

Many normal-sighted persons might object to the inclusion of some of the colours on the orange card, but this card clearly shows the colours which may be taken as a match. Fine distinctions are not wanted. The series of colours I have selected and arranged so as to confuse the colour blind and force them to be guided by their colour perception, whilst the quantity of colour is amply sufficient for the normal sighted to pick out the colours with the greatest ease. The cards should be arranged irregularly on a white cloth in a good light. The two most important test colours are the orange and violet, Nos. I. and II. The person examined should be asked to point out the shades of colour similar to No. I (orange). A piece of paper rolled to a point should be used for this purpose. If he does this correctly he probably possesses normal colour perception. If, however, he matches the test with reds or pinks he is more or less colour blind, at best belonging to the pentachromic class. If, in addition, he matches the violet test, No. II., with blue, he at least belongs to the tetrachromic class. The trichromic, in addition, may match the blue-green test, No. III., with brown and grey. The dichromic will match the orange test, No. I., with yellow-green and yellow-brown. Similar mistakes will be made to those described in connexion with the Classification Test. The examinee should be asked to name all the colours on one of the cards. He should also be asked to point out on which of the cards the four test colours are to be found and which contain none of the test colour. The examiner should continually change the order of the cards. Most of the varieties of the colour blind will be readily detected in this way.

The special advantages of this test are: 1. The colour blind can be ranged definitely in their proper classes. 2. Central scotoma can be detected with its aid. 3. The series of colours are arranged so as to confuse the colour blind, whilst the normal sighted easily match the test colours. 4. On account of the introduction of different materials the relative luminosity and saturation of colours does not serve as a guide to the colour blind. 5. Portability. 6. The wools and silks are kept clean. 7. An important colour is not likely to be lost.

3 *The colour-perception spectrometer.*[4]—(*a*) *Description of apparatus.*—This instrument is a spectrometer so arranged as to make it possible to expose to view in the eyepiece the portion of a spectrum between any two desired wave-lengths (Fig. 1). In the focal of the telescope are two adjustable shutters with vertical edges; the shutters can be moved into the field from right and left respectively, each by its own micrometer screw, and to each screw is attached a drum (Fig. 2), the one being on the right and the other on the left of the telescope. On each of these drums is cut a helical slot in which runs an index, and the drum is engraved in such a manner that the reading of the index gives the position in the spectrum of the corresponding shutter in wave-lengths direct. Thus it will be seen that if, for instance, the reading on the left drumhead is 5320, and that on the right drumhead is 5920, the region of the spectrum from wave-length 5320 to wave length 5950 is exposed to view in the eyepiece.

FIG. 1.



The colour-perception spectrometer.

FIG. 2.

Drum attachable to micrometer screw.

(*b*) *Directions for using the instrument.*—It should be used, as far as possible, with a known quality and intensity of light. A small oil-lamp is quite suitable for the purpose. The observer should first ascertain the exact position of the termination of the red end of the spectrum, the left-hand shutter being moved across until every trace of red just disappears. The position of the pointer on the left-hand drum is noted and the wave-length recorded. The left drum is then moved so that the shutter is more towards the middle of the spectrum. The right-hand drum is then moved until the pointer indicates the wave-length recorded as the termination of the red end of the spectrum. The observer then moves the left-hand shutter in and out until he obtains

[4] Made by A. Hilger, 75A, Camden-road, London, N.W.

the largest portion of red, which appears absolutely monochromatic to him, no notice being taken of variations in brightness, but only in hue. The position of the index on the left-hand drum is recorded. The left-hand shutter is then moved towards the violet end of the spectrum, the right-hand shutter being placed at the position previously occupied by the left-hand shutter. In this way the whole of the spectrum is traversed until the termination of the violet end of the spectrum is finally ascertained with the right-hand shutter. The variation of the size of the patches and the terminations of the spectrum with different intensities of light can be noted. The instrument can also be used for ascertaining the exact position and size of the neutral patch in dichromics, the position of greatest luminosity, and the size and extent of pure colours. When it is used to test colour-blindness the examinee should first be shown some portion of the interior of the spectrum, and then asked to name the various colours which he sees. In this way he will have no clue to the colours which are being shown him.

*Objections to other tests for colour blindness.*—The tests which have been proposed for colour blindness are very numerous, but some are so defective that it is rare to detect a single colour-blind person with them. I have, for instance, tested men whom I knew to be colour blind with certain lanterns, with the result that not a single one was detected. In these so-called tests all the requirements of a test and facts of colour blindness have been neglected. I must, however, refer to three tests constructed by exceptionally able men, each with considerable knowledge of the subject. I refer to the tests of Professor Holmgren, Professor Stilling, and Professor Nagel.

All these tests can be passed at the first attempt without coaching by certain dangerously colour-blind persons, chiefly varieties not known to the inventors, but the chief defect of each is that it is very easy to coach a colour blind person to pass it. The surgeon to one of our largest railway companies told me that when they used Holmgren's test they rejected one man in 300, but with my lantern 12 in the same number. All these three tests are much better tests when the persons to be examined have not seen them before. A colour-blind man may make only one mistake—say, for instance, as in a case I examined the other day with Nagel's test (last edition), he passes the test perfectly with the exception of one mistake, that of calling a grey on one card green. All he has to do is to look for some distinguishing mark on this card in order to go through the test with the ease and certainty of a normal-sighted person. It is the same with Stilling's letters, he has only to note the letter which he was not able to read and the appearance of the card. A normal-sighted man or woman would readily help him. The confusion of green and grey does not appeal to the average man as a serious defect, especially when he sees his friend go through the rest of the test perfectly. He says to himself, I suppose, he sees a tinge of green in that grey. The same man would rightly regard it as a most iniquitous proceeding to endeavour to coach his friend through a test when he had seen him mistake a red for a green light.

Holmgren's test rejects a large number of normal-sighted persons, as may be seen by the reports of the Board of Trade; about 50 per cent. of those who appeal are found to be normal sighted and to have been rejected wrongly.

THE CONVALESCENT HOMES ASSOCIATION.—This association has just issued a useful list of convalescent and other homes receiving London patients with particulars of the terms of admission and other useful information. The list includes homes for men, women, and children, homes for children only, patients requiring surgical treatment, homes for mothers and infants, homes for gentlewomen, and sanatoriums for consumptive patients, the terms of residence ranging from 3*s.* 6*d.* per week upwards. The association points out that they accept no responsibility with regard to the institutions named, and that inclusion in the list does not necessarily imply recommendation nor exclusion the reverse. The compilation will, however, we think, prove of great utility to medical practitioners when selecting a convalescent home for their patients, especially those of limited means. The book can be obtained at the offices of the association, 32, Sackville-street, London, W., at the price of 6*d.*

# THE PATHOLOGY AND TREATMENT OF INJURIES CAUSED BY ELECTRICITY.[1]

BY SIR THOMAS OLIVER, M.A. DURH., M.D. GLASG., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE.

THE increasing use of electricity is introducing fresh dangers within our midst. As an illuminating agent it stands supreme and for motive power its utility is unquestioned. Electricity is therefore likely to have an extended sphere of application in the future. Its powers of maiming the body and of immediately destroying life are well known. Since 1902, the year in which death by electricity became notifiable to the Home Office, the following are the numbers of fatal cases which have been reported: In 1902, 7; in 1903, 4; in 1904, 6; in 1905, 7; in 1906, 10; in 1907, 11; in 1908, 2; and in 1909, 12. Notwithstanding the precautions which have been taken the number of fatal cases has increased, but this is largely in consequence of more persons being brought into contact with electricity. If we add to the above the many cases in which both minor and severe injuries have been received during recent years we can appreciate the need of having regulations drawn out for the guidance and safety of workmen. It is only because the majority of practical electricians are a well-educated and careful class of workmen that accidents are not more frequent. It is the unskilled labourers who contribute largely to the death roll. Many of the accidents are due to inadvertent contact with exposed parts of highly charged metal not sufficiently insulated or to workmen during alterations touching wires into which the current previously withdrawn has been unexpectedly diverted. Usually it is only a single person who is thus fatally caught in the round of the current, but the danger extends to all who unprotected attempt to succour him. The escape of electrical currents, too, under particular circumstances may become the cause of a catastrophe of an appalling nature. How far the West Stanley explosion of nearly two years ago, in which 166 lives were lost, was the result of an electric spark having fired the coal dust in the mine it is impossible to say. Electricity cannot be trifled with. Experience and experiment alike point the way by which some of the dangers incidental to its use may be averted. The danger depends upon the amount of current passing through the body, the kind of contact, and the insulated position of the individual at the particular time. If he is wearing damp boots, standing on wet soil, and his skin is moist, all of these will aggravate the effects of an electrical shock. The danger is not one of high potentiality of current alone, but of it *plus* the conditions under which the current is received.

Voltage in electrical parlance means pressure or electromotive force. It is difficult to say what voltage is fatal to man. In the United States where the current has been used for the electrocution of criminals not less than 1450 volts has been insisted upon, but in some instances death was not instantaneous. As regards illumination of factories, there is one case on record where a lad on taking hold of a lamp which had been burning badly was killed by a 200 volts alternating current. On the other hand, contact with currents carrying 2000 volts pressure has been made and no serious injury followed. Although opinions are divided as to the comparative dangers of "continuous" and "alternating" currents, it is generally believed that of the two the "alternating" current is the more dangerous. Between 1902 and 1908 there were three fatalities due to continuous currents of 250 volts and lower, whereas during the same period 30 deaths were the consequence of alternating currents. The Board of Trade considers alternating currents to be twice as dangerous as continuous. There is no proof that any one man is more susceptible to electric shock than another. It is, as already stated, rather a question of good or bad contact, dampness of skin, and amount of current entering the body. A dry skin offers greater resistance to the entrance of electrical currents than the same when moist. Where the contact is good and conditions

[1] Part of a clinical lecture delivered in the Royal Victoria Infirmary, Newcastle-upon-Tyne, on Nov. 23rd, 1910.

Mammary Cancer, said he should consider, first, the diagnosis of the various mammary tumours; secondly, their genetic relationship to one another and in what circumstances innocent tumours might develop into malignant type; and thirdly, the possible steps which might be taken to prevent innocent tumours from becoming malignant. By means of lantern slides of microscopic and macroscopic sections, Mr. Handley clearly demonstrated the pathological anatomy of fibro-adenomata through their varying stages. He quoted and showed slides of pathological specimens showing the relationship between fibro-adenoma and carcinoma—e.g., in one case carcinoma developed in a breast six months after the removal of an innocent fibro-adenoma; also, in the museum of St. Bartholomew's Hospital there is a specimen of a fibro-adenoma with a carcinoma in the centre of it. Therefore he always advised the removal of fibro-adenoma, and in addition he always swabbed out the cavity caused by its removal with some strong antiseptic solution so as to destroy any stray cells of the tumour left in its removal. On the other hand, types of soft fibro-adenoma sometimes became very rapid in their growth, and he had no doubt these occasionally took on a sarcomatous type. In the same way Mr. Handley followed out the course of the growth of duct papilloma, and showed a beautiful example with a duct papilloma projecting in the lumen of the duct, and having eroded the opposite wall; beyond this were undoubted signs of duct cancer. He advised the complete removal of the breast in all cases of duct papilloma, in fact, wherever there was serous discharge at the nipple. Turning to the inflammatory tumours, chronic mastitis was probably the chief precursor of malignant disease. He regarded Paget's disease as being carcinomatous from the commencement and only secondly becoming eczematous. Mr. Handley pointed out that "pig skin" was not always malignant, but might be due to syphilis or tubercle as it was caused by lymphatic obstruction. The pits were the openings of the sweat glands where the skin was tied down to the subcutaneous tissue.

Mr. R. G. HOGARTH proposed a vote of thanks to Mr. Handley and Dr. C. H. CATTLE seconded this.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SECTION OF SURGERY.

*Two Unusual Gall-bladder Cases.—Congenital Fistulæ.*

A MEETING of this section was held on Jan. 20th, Mr. SETON PRINGLE being in the chair.

Dr. W. S. HAUGHTON read a paper on Two Unusual Gall-bladder Cases: (1) Foreign Body; (2) Typhoid Carrier. In the first case the patient had had well-marked biliary colic in two previous years, with severe gastric disturbance and pain during the intervals. A very small thickened gall-bladder, with adhesions to liver and stomach too dense to permit removal without stomach resection, was found. The gall-bladder contained two small calculi and a bristle, resembling a tooth-brush bristle, half an inch long and with a piece of thread tightly rolled round one end, which might have ulcerated through the stomach-wall. In the second case there was no definite history of typhoid fever, though there had been intermittent symptoms of partial intestinal obstruction for six years. Operation revealed a pear-shaped gall-bladder, the cystic duct forming a long pedicle. The walls were half an inch thick. It contained 18 calculi and much white milky fluid containing a pure culture of typhoid bacilli. The blood was highly agglutinating.—Dr. W. M. CROFTON said that, in spite of the absence of a history of typhoid fever, an anomalous febrile illness in a person who had come from Cairo—a hotbed of typhoid fever—was suspicious. No conveyance of the disease was proved.—Mr. SETON PRINGLE inquired whether the area of tenderness opposite the tenth and eleventh dorsal spines on the right side, said by Boas to be present in all gall-stone cases, had been found. He himself had found it only once, in spite of constant search. He suggested that it would be safer and simpler and would lessen the risk of sepsis to remove the gall-bladder unopened in such a case as the present. As the cystic duct was closed in the second case the woman might not be a carrier. Infection of the gall-bladder, he thought, might occur through the mouth without typhoid fever.—Dr. H. STOKES asked why it was so difficult to pass a probe down the common bile-duct in the dissecting-room when it was easy in the living subject. Also whether the typhoid bacillus could live and multiply in a patient with marked agglutinating power.—Mr. A. J. MCAULEY BLAYNEY did not think Boas's tenderness to be relied on for diagnosis. He had never been able to find it himself. He had often had difficulty in passing a probe into the cystic duct in the living, probably from a valve-like condition of the mucous membrane. From the high agglutinating power the patient must have absorbed a considerable amount of typhoid poison. She had probably had typhoid fever.—Dr. T. P. C. KIRKPATRICK said that there was no evidence that this patient excreted typhoid bacilli, so she could not properly be called a typhoid carrier.—Dr. W. PEARSON said that, as to removal of the gall-bladder, the questions were: 1. If not removed would it be a source of danger to the patient? 2. Was anything to be gained by leaving it behind? In contracted gall-bladder the likelihood of cancerous changes suggested removal, as did also stricture of the cystic duct. There was no evidence that the gall-bladder had any other function than as a reservoir for bile, while Opie's experiments showed that mucus rendered the bile innocuous. Therefore, as cholecystectomy was more serious than cholecystostomy, in suitable cases of cholecystitis the bladder should be left.—Mr. K. E. L. G. GUNN reported an instance in support of the contention that it was not sound practice to remove the gall-bladder in every case.—Mr. R. A. STONEY said that there was often difficulty in passing the probe in the living from adhesions or the tortuous course of the cystic duct. When the bladder was fairly normal it was better to leave it, especially in young patients, but with well-marked changes it was better to remove it. As to the relative merits of cholecystectomy and cholecystostomy, statistics could not be relied on, because the former was done in severe cases, the latter in milder ones.—Mr. HAUGHTON and Dr. CROFTON replied.

Dr. J. H. P. BOYD BARRETT read a paper on Congenital Fistulæ, confining his remarks to fistulæ of the umbilicus, external ear, preauricular area, and coccygeal area. Laparotomy was suggested in umbilical fistulæ where the possibility of adherence of the ileum to the umbilicus through a Meckel's diverticulum existed.—Mr. STONEY related two cases of sacral fistula simulating ischio-rectal abscess. In the first case the abscess had been twice opened. Mr. Stoney then opened it and found the fistula lined with skin, which had probably formed the route of infection from the anus. The abscess was scraped out and the fistula dissected out. There had been no recurrence.—Mr. GUNN related a case from the Adelaide Hospital to show that it was not so easy as Dr. Barrett had implied to distinguish between umbilical fistula and adenoma.—Dr. STOKES and Dr. PEARSON related cases.—Mr. SETON PRINGLE suggested that where the diagnosis lay between patent urachus and intestinal fistula, it might be well to give the patient methylene blue and see if the escaping fluid became coloured.—Dr. BARRETT replied.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.—A meeting of this society was held on Feb. 3rd, Professor R. Muir, the President, being in the chair.—Professor R. Stockman read a paper on the Clinical Symptoms and Treatment of Chronic Subcutaneous Fibrosis. This condition is, in Professor Stockman's experience, a very common one, and is secondary to various acute and chronic affections—e.g., acute rheumatism, influenza, general gonococcal infections, and mucous colitis. It consists in an irregularly spread, patchy, chronic inflammation of the subcutaneous connective tissue, which involves also the small peripheral nerves and blood-vessels. Microscopic examination of an affected patch shows the fibrous tissue thicker and denser than normal, with numerous fibroblasts, the small nerve twigs running through it being in a condition of interstitial inflammation, and the blood-vessels showing peri- and endo-arteritis. Implication of nerves gives rise to so-called "rheumatic" symptoms, aching, pain, stiffness, neuralgia, numbness, tingling, chilliness, lack of vigour. An erroneous diagnosis of neurasthenia is often made. The condition is common at all ages, in both sexes, and quite independently of obesity. The thickenings are readily felt and usually tender on pressure. When they occur in stout

persons the subcutaneous fat tends to form larger or smaller masses round them. Such masses are deposited mostly in the ordinary situations of fat accumulation, especially on the abdomen, hips, and thighs, and are often very painful on pressure, the condition then being identical with that described by Dercum as "adiposis dolorosa." Treatment in the case of thin patients consists in massage, daily exercises directed to stretching the altered fibrous connective tissue and to accustom it to movement, along with an active open-air life. In the case of stout or plump persons, the superabundant fat must first be removed by a more or less strict diabetic diet, and the administration of thyroid gland or liquid extract of fucus vesiculosus. Perseverance on these lines for some months usually results in a cure, or, at least, considerable improvement; but in cases where the subcutaneous fibrous tissue is dense and widespread with little fat, very moderate betterment is to be expected.—Dr. T. W. Dewar read a paper on the Treatment of Phthisis by means of the Intravenous Injection of an Ethereal Solution of Iodoform. After ten years' experience of this method of treatment Dr. Dewar's belief is that in an early uncomplicated case of pulmonary tuberculosis with good veins, three or four months of iodoform treatment, without special diet or rest, will effect a cure. Such a case would be one presenting the physical signs of apical consolidation on one side. In more advanced disease, with breaking down in one upper lobe and consolidation in some part of the other lung, iodoform treatment for a year or more, together with modified rest and extra diet, will also succeed. Even in far advanced cases with vomicæ improvement occurs. Dr. Dewar has treated several men who prior to receiving injections were unable to work, but who soon resumed it, and have been able to continue it when undergoing treatment. The doses given vary from ¼ to 1 grain of iodoform, and are generally administered three times a week. The occurrence of toxic symptoms, increased temperature, or increase of sputum are indications for reduction of the dose. How iodoform in such small doses can counteract the virulent poison of the tubercle bacillus is unknown. Dr. Dewar suggests that it may act germicidally as its own molecule; or from its decomposition in the body nascent free formic aldehyde and nascent free iodine, both powerful antiseptics, may be formed; or it may stimulate phagocytosis; or it may act as a toxin, inducing the formation of an antitoxin inimical to the growth of the tubercle bacillus. Dr. Dewar has had no success with tuberculin treatment, and stated reasons for his belief that no success is to be expected. As the results of sanatorium treatment admittedly leave much to be desired, he urged that the iodoform treatment be given a thorough trial.—Dr. John Guy said that he had at present under his treatment in the Bridge of Weir Sanatorium 35 cases of phthisis, and he showed the records of 12 of these who had been under treatment for periods varying from 9 to 22 weeks. He had failed to see any decided benefit accruing, and some of the cases had become continuously worse while being treated.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Feb. 3rd, Dr. Leonard Williams, the President, being in the chair.—Dr. Eardley Holland read a paper on the Diseases of Women which are directly due to Childbirth and their Prophylaxis during Labour and the Puerperium. He said that 50 per cent. of the cases of women with gynæcological diseases are due to trouble at labour or in the puerperium and are preventable by proper management. Lacerations of the perineum are generally due to lack of knowledge of the way to preserve the perineum; and severe lacerations are caused by delivery of the head in unreduced occipito-posterior presentations and by too rapid delivery of the head by forceps. Lacerations should always be sutured, otherwise they leave raw surfaces for the entrance of bacteria. Prolapse of the uterus is not due to lacerations of the perineum, but to injuries to the pelvic floor. The levator ani is the chief support of the uterus and forms a muscular diaphragm on which the head rests, and if the head passes through too quickly fibres of the levator ani get torn. Lacerations of the cervix are due to too rapid passage of the head through the undilated os, hence the application of forceps before full dilatation of the os is absolutely contra-indicated. Post-partum hæmorrhage occurring when the uterus is small and hard as a cricket-ball is due to severe laceration of the cervix. Subinvolution is one of the commonest diseases and mostly occurs in women with large families who get up too early. It is associated with congestion of the uterus, which is due to retention of blood clots, bits of placenta, and membranes. Hence, to prevent subinvolution, care should be taken to empty the uterus. Of all the minor diseases of women a permanent retroflexion is the most troublesome. The uterus is always subinvoluted and congested and causes painful menstruation, pain on coitus, leucorrhœa, &c. 75 per cent. of all retroflexions arise in the puerperium and are essentially preventable and curable. They occur mostly in primiparæ and arise on the eighth to the twelfth day of the puerperium. Treatment consists of rest in bed and replacement of the retroflexed uterus with the finger, the subinvolution being treated with very hot vaginal douches and big doses of ergot and strychnine. Generally, to prevent puerperal diseases, thorough asepsis during labour should be aimed at, and as few examinations as possible should be made. In the second stage of labour the patient should never be allowed to go more than two hours. If the head is presenting and there are no contra-indications forceps should be applied. For if the patient is left longer resistance is lowered, needless pain is suffered, asphyxiation of the child is risked, &c. The third stage ought to be left to nature. The hand ought to be kept lightly on the fundus of the uterus, but not heavily pressed. After expulsion of the placenta the hand should be kept on the uterus for 15 minutes and the uterus should be rubbed and squeezed so as to get rid of blood clots, bits of placenta, and membranes.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 2nd, Dr. F. Hinds, the President, being in the chair.—Dr. A. W. Williams showed a case of Rodent Ulcer near the inner canthus, which had been treated by means of X rays. This had nearly healed the ulcer, but there was left a resistant point which a single application of solid $CO_2$ over lead-foil had cured.—Dr. R. J. Ryle moved, and Dr. J. Lambert seconded, the following resolution:—

> That the absence of control of the feeble-minded is a contributory factor of great importance in relation to crime, to immorality, and to the problem of unemployment, and that the lack of control, because of the greater fecundity of the feeble-minded, seriously reduces the mean average of the health, the intelligence, the morality, and the physique of the race, and they therefore urge upon His Majesty's Government the necessity of placing in some authority, subject to such safeguards as may be thought advisable, the permanent care and control of these unfortunates; and that copies of this be forwarded to the Prime Minister, the President of the Board of Education, the President of the Local Government Board, and the borough Members of Parliament.

—A discussion took place in which the following members spoke: Dr. L. A. Parry, Dr. W. Furner, Mr. H. H. Taylor, Mr. T. H. Ionides, Dr. C. H. Benham, the President, Dr. E. Hobhouse, Mr. H. Stott, Dr. Helen Boyle, and Dr. C. F. Bailey.—The resolution was then carried.

WESTMINSTER CITY COUNCIL AND MEDICAL CERTIFICATES FOR WORKMEN.—The question of certification of illness and payment of sick pay to workmen formed the subject of a report presented to the meeting of the Westminster city council on Feb. 2nd by the general purposes committee. It appeared that the practice subsisting under the standing orders of the council was that workmen were entitled to certain sick pay in the case of illness or accident subject to the production of a weekly medical certificate from the Poor-law medical officer of the district in which the workmen resided. The cost of these certificates (2*s.* 6*d.* each) was borne by the council and had annually averaged during the last five years £237. In June of last year the council decided that where a workman's illness was of longer duration than one week he should also, at his own expense, produce a weekly certificate from the doctor by whom he was being attended for his illness to the effect that he was receiving medical treatment. The latter certificate met all the council's requirements, and it was agreed that the certificate from the Poor-law medical officer should be dispensed with, and notice was ordered to be given to the Poor-law district medical officers terminating the arrangement under which they issued weekly certificates. Workmen in future would therefore be required to obtain at their own expense certificates from a medical practitioner in the event of being unable to perform their duties.

*The Treatment of Cataract.* By Lieutenant-Colonel HENRY SMITH, B.A., M.D. R U.I., M.Ch., Indian Medical Service. Calcutta: Thacker, Spink, and Co. 1910. Pp. 121.

Lieutenant-Colonel Henry Smith's strenuous advocacy of the intracapsular method of extracting cataract is familiar to ophthalmologists all over the world. It is a merciless assault on the practice of the most distinguished surgeons since Daviel first extracted a cataract in 1750. Such temerity can be justified only by reasoned argument and proved success. If these had not been forthcoming in appreciable degree Lieutenant-Colonel Smith would not have obtained the following of disciples who act as his lieutenants in India and his missionaries in the United States. We particularly welcome this work on the whole range of the treatment of cataract in all its forms, because it enables us to obtain a clearer and juster conception of the author's attitude to the classical method of extraction which he has almost, if not entirely, abandoned. In his scattered papers and addresses the statement of his thesis is so dogmatic and polemical that, however willingly these defects are condoned and excused as the expression of a perfervid enthusiasm, they have militated against a calm and judicial estimate of his claims. Here he has a larger canvas and is compelled to depict details with greater regard to their true perspective. The dogmatism is still apparent, but it is less misplaced in a didactic treatise.

Much of the book is necessarily devoted to the treatment of forms of cataract for which the intracapsular method is unsuited. It differs little except in comparatively unimportant details from the same sections in other textbooks. A lengthy chapter devoted to Daviel's operation, as the author prefers to call the usual method of extraction, shows that he is fully conversant both in practice and theory with its admitted defects. We are not inclined to view as lightly the many improvements in technique which have been introduced since Daviel's time, and which in our opinion make the name "Daviel's operation" inadvisable. A very careful consideration of the *pros* and *cons* of this operation and of the intracapsular method confirms us in the opinion that the latter is eminently suited for the extraction of immature cataract if only the majority of ophthalmic surgeons could acquire the dexterity to command such success as Lieutenant-Colonel Smith claims for himself. But on his own showing this can only be attained by practical instruction from a master of the art, and he must admit that few are in a position to make a pilgrimage to India for the purpose. The book does not succeed in convincing us that the operation should be undertaken for mature or hyper-mature cataract, at any rate by the weaker brethren in the West. We say unhesitatingly, however, that every ophthalmic surgeon ought to read the book and weigh the arguments for himself with the seriousness they merit.

---

*Normal Histology, with Special Reference to the Structure of the Human Body.* By GEORGE A. PIERSOL, M.D., Sc.D., Professor of Anatomy in the University of Pennsylvania. With 438 illustrations, many of which are in colours. Eighth edition. London and Philadelphia: J. B. Lippincott Company. Pp. 418. Price 15*s.* net.

THE eighth edition is a great advance on its earlier predecessors. It has been rewritten and greatly improved. The author remarks that histology often has its place at the beginning of a medical curriculum, so that the student is required to study microscopical details of organs before he has become acquainted with their gross anatomy. For this reason—and we think wisely—the author, to minimise this deficiency, has prefaced some of the histological descriptions with references to the "macroscopic features" whenever such explanations seem desirable, as, for example, in the chapters on the central nervous system. The treatise, be it noted, has special reference to the structure of the human body.

The illustrations are admirably and most faithfully reproduced, most of them original. Indeed, the author has introduced many illustrations which are not usually found in histological text-books. We may mention a few amongst many: developing blood-vessels in embryonic subcutaneous tissues, section of leaflet of tricuspid valve and of lymphatic valves, perivascular lymph spaces of the retina, coccygeal gland, wall of the pharynx showing the pharyngeal tonsil, the gall-bladder, velum interpositum, pineal body with its calcareous concretions, external auditory canal, cervical mucous membrane of the uterus, and the labia. The figures of injected organs are particularly good, and give the student an excellent idea of the manner in which the main vessels get into a dominant position in an organ from which they can most efficiently supply its individual parts with blood. In the coloured diagrams of the hepatic lobule the relative size of the hepatic artery and portal vein might be improved. The illustrations throughout reach a high standard of excellence, while the text is also admirable, not too diffuse, but giving the salient features of the various structures with sufficient fulness to impress important details without wearying minutiæ. An additional commendable feature is that in every case the magnifying power is appended to the original illustrations, which were drawn with the aid of the camera lucida by Mr. Louis Schmidt, obviously a faithful reproducer of typical and excellent preparations.

Professor Piersol deserves unstinted praise for the excellence of his treatise; it is one of the best and most useful in the English language. A short appendix is added concerning microscopical technique, presenting a few methods which are satisfactory and thoroughly trustworthy for the majority of histological examinations. We commend most heartily this work to all interested in the histology of the human body.

*Practical Motherhood.* By HELEN Y. CAMPBELL, L.R.C.P. & S. Edin., L.F.P.S. Glasg. London: Longmans, Green, and Co.; Johannesburg: R. L. Esson and Co. 1910. Pp. 535. Price 7*s.* 6*d.*

WE do not gather from a careful perusal of this book that Dr. Helen Campbell is entitled by experience to undertake so ambitious a task as writing a book of 500 pages on the subject of practical motherhood. Nevertheless, in this case the reader benefits by the compensatory care which the author has clearly taken to consult the best authorities, to quote them accurately, and, so to speak, pick their brains to the greatest advantage. No doubt, the reader will appreciate the fact that the text is not encumbered with particulars or references to the sources of information.

The subject matter is well arranged, clearly and simply stated, and in most respects accurate. The first part is concerned with the Hygiene of Pregnancy, Infancy, and Childhood, the second part with Feeding in Infancy and Childhood, the third part with Difficulties and Illness in Infancy and Childhood, the fourth part with the Development and Training of the Mind in Childhood, while the fifth and final section is devoted to the School Age. In the preface Dr. Campbell states: "I am of opinion that the practical knowledge which we owe to the work of our several pediatrists, in so far as it concerns the feeding of the healthy infants, should belong to every mother, and that if its essentials were universally realised difficult feeding cases would be much more rare." This is not only

the motive of the author's plain talking in Section II., but it is clearly the principle which guides her in the chapters which deal with obstetrics and pedagogy. "How much is good for mothers to know" is a question which has always vexed the mind of the medical profession, but where angels have fear to tread Dr. Campbell has entered boldly, and she has told them everything, and what she has told them is perfectly true—but is it good for them?

The best section is undoubtedly that which is concerned with the feeding of infants. The instructions at first sight appear a little complicated, but if the whole section is read no difficulty will be found in following out all the details with complete accuracy. The whole method is founded on a percentage basis, but the reader is not confused by tables or figures. The goal at which the author aims is to feed infants on milk and cream mixtures, but she realises and explains to her readers that the infant has to learn to digest cow's milk in the same way that it has to learn many other functions.

As a work which is admittedly written for the lay public and for mothers this book is unusually accurate and scientific. It is also so practical that medical men in general practice could only assimilate its contents with advantage to their patients.

*Sewage Disposal in the Tropics.* By W. WESLEY CLEMESHA, M.D. Vict., D.P.H., Major I.M.S., Sanitary Commissioner, Bengal; Professor of Hygiene, Calcutta University; late Officiating Sanitary Commissioner, Madras. Calcutta and Simla: Thacker, Spink, and Co. London: W. Thacker and Co. 1910. Pp. 232. Price 15*s.* net.

IT is very interesting to learn from those who have studied closely the practical side of the subject that the introduction of the biological method of the disposal of the sewage into western countries has given remarkable results, so that although all that was at first claimed for the process may not now be accepted there can be no doubt that to use certain organisms for converting offensive excrementitious matter into simple substances is, in the main, a success. To describe the measure of success reached is the purport of Major Clemesha's work, and he has written an account of the subject which will be valuable to all those engaged in practical sanitation, more particularly as the work is based upon a strenuous laboratory and practical study. The problem of sewage disposal presents in the East difficulties which do not exist in western countries. The habits of the people themselves constitute a very marked difference from those of the inhabitants of Europe. In rural areas practically no method of disposal of night-soil and urine exists except the one that dates back thousands of years ago, when it was laid down in the Shastra that every individual should go out early in the morning to some waste land for the purposes of nature. That simple method must obviously be abandoned when the rural district gives way to the town, and when a thickly populated area is rapidly formed. This experience has been repeated again and again in the modern history of India, and so a definite scheme of sanitation has to be devised, which has commonly taken the shape of a system of latrines, "public and private, conserved by hand." The water-carriage system is only installed in the very largest cities. The hand-removal system must remain usual for the present, though here and there attempts are being made to supplant it by water-carriage. Meantime, splendid work is being done to free the hand-removal system from reproach by applying to it the principles of up-to-date biological treatment. It is in this direction that Major Clemesha and his colleague, Dr. Fowler, are doing admirable work in the great cause of sanitation in an enormous empire, and this volume shows that by the use of the biological method, when certain conditions are observed, the whole of the excreta from a community can be satisfactorily disposed of in specially designed latrines, thereby avoiding the nuisance and the dangers to health involved by the removal of a large mass of putrescible material. The chapters on the design of the latrine, the tank, the chemical action in the tank, the arrangement of contact beds, the aerobic and anaerobic treatment of sewage, the septic tank effluent, all show a remarkable attention to detail and an intimate knowledge of the factors which must be taken into account if success is to be assured. The book altogether is a valuable practical contribution to the problem of sanitation in the East and should help very materially the advancement of a great and most important sanitary campaign.

---

*Manual of Operative Surgery.* By JOHN FAIRBAIRN BINNIE, A.M., C.M. Aberd., Professor of Surgery, Kansas State University, Kansas City. Vol. II., Vascular System, Bones and Joints, Amputations. Fourth edition, revised and enlarged, with 550 illustrations. London: H. K. Lewis. 1910. Pp. 553. Price 14*s.* net.

IT would have been difficult to express a higher opinion of a work on operative surgery than that we have put forth on previous appearances of this work. The book occupies a position amongst works on operative surgery. It would be of very little value to the junior student, but to the senior student, and especially to the surgeon engaged in the active work of his profession, it is just what is wanted to enable him to be fully conversant with the most recent advances. It is written in a style which enables the reader to see almost at a glance the essential points connected with any operation and to compare readily the relative merits of the different methods of surgical treatment. This second volume completes this edition of the work. The plan is admirable, and it has been admirably carried out.

---

*Ergebnisse der Chirurgie und Orthopädie. (Contributions to Surgery and Orthopædics.)* Herausgegeben von Erwin Payr of Greifswald und Hermann Küttner of Breslau. Vol. I. With 148 illustrations in the text and 4 plates. Berlin: Julius Springer. 1910. Pp. 525. Price 20 marks; bound, 22 50 marks.

THIS is the first volume of an attempt to put forth the latest facts and series connected with special subjects in surgery. In each case an author has been chosen, thoroughly familiar with the subject on which he has to write and fully competent to record its latest developments. In each case the article is preceded by the recent bibliography which represents the material on which the article has been based, though naturally the author has supplied original information himself.

The first subject dealt with is the transplantation of vessels and organs by means of suture of the vessels, and it has been written by Professor Rudolf Stich of Bonn. It is provided with 34 illustrations and it describes practically all that is known at the present time of the very difficult subject of suture of vessels, especially as applied to the transplantations of organs. Professor Hermann Küttner of Breslau has written on Circumscribed Myositis Ossificans. He recognises three forms—the traumatic variety, a non-traumatic variety, and a neurotic form. Dr. Hermann Coenen of Breslau has written an article on Opsonins, in which he describes the technique and discusses the value of the method. Several other valuable papers are contained in the volume. Thus Professor B. Bardenheuer and Professor R. Graessner have written on the Treatment of Fractures, Dr. Josef Hertle on the Methods of Replacing Deficiencies of the Skull, Dr. Felix Landois on the Parathyroid Glands, Dr.

E. Melchior on Exophthalmic Goitre, Professor Ferdinand Sauerbruch on the Present State of the Employment of Differences of Atmospheric Pressure in Operations on the Organs contained in the Thorax, Dr. Günther von Saal on Benign Tumours of the Breast, Dr. Martin Kirschner on the Operative Treatment of Umbilical Hernia, and Dr. W. Hirt on Hypertrophy of the Prostate. The articles naturally differ in importance, but there is not one of them which does not give a clear exposition of its subject.

It is to be hoped that future issues will maintain the high standard set by this volume, and we think that the editors, Dr. Payr and Dr. Küttner, have inaugurated a useful addition to surgical literature. One suggestion we would like to make. Many surgeons will wish to separate the volume into its constituent papers, and this will be much easier if each article is made to begin on a right hand page.

---

*A Manual of Physiology, with Practical Exercises.* By G. N. STEWART, M.A., M D. Edin., D.P.H. Camb., Professor of Experimental Medicine in Western Reserve University, Cleveland. Sixth edition. With coloured plates (2) and 449 other illustrations. London: Baillière, Tindall, and Cox. 1910. Pp. 1064. Price 18*s.* net.

THE first edition was published in 1896; the fourth in 1900; the fifth in 1906, with 911 pages and 395 illustrations; and now we have the sixth edition, with the illustrations increased to 449 and 1064 pages of text. The general arrangements are retained, but much has been rewritten—e.g., the introductory chapter on proteins and the general chemistry of living matter. The histology of leucocytes has been relegated to small type to make room for additions to such matters as viscosity of blood, "titratable" alkalinity of blood or serum, hæmolysis and allied phenomena connected with blood. "Metschnikoff" (p. 52) is still written with an "s." In the practical exercises on blood slight changes are made and the figure of a hæmatocrit is added. Altogether about 11 pages are added to the introduction and Chapter I., on the blood and lymph.

Without going into changes of detail in the successive chapters, we have compared this edition with its predecessor, and we find that it has been most thoroughly revised and brought quite up to date by judicious additions. We think that a few outstanding dates in the history of the subject might be added, so that the student might know how recent are some of the most fundamental facts—e.g., the experiments of Stannius, the discovery of vaso-motor nerves, the vaso-dilation action of the chorda tympani by Bernard, when Hales first measured the blood pressure and Ludwig recorded it, when Eckhard discovered the nervus erigens, and Addison made his epoch-marking discoveries in relation to the suprarenal capsules, &c., as well as those of older date, such as the experiment of Mariotte.

Full advantage has been taken by the author of the newer researches on the *a.-v.* bundle, and the observations on pulsatile phenomena in veins. The author gives every here and there a keen critical account of contending theories—e.g., Is the beat of the heart neurogenic or myogenic? What are the processes connected with the secretion of urine? The summaries printed in italics are useful. The rice ordeal of India might be added under salivary secretion, and on p. 361 we should expect a note on the remarkable acid salivary secretion of Dolium galea. Under muscle rigor we do not find any account of Sommer's movements. On p. 468 is Berkely a misprint for Berkley?

The central nervous system now occupies 145 pages instead of 120. The author has woven in the leading new facts recorded in Sherrington's "Integrative Action of the Nervous System" and Campbell's work on the cerebrum, including notice of the question recently reopened by Marie as to the relation of aphasia to lesions of the inferior frontal convolution, and of the autonomic nervous system of Langley. A very full account is given of the phenomena observed after section of cutaneous nerves by Trotter and Davies, following on the pioneer work of Head, and the student is "warned that the distinction of protopathic and epicritic sensibility has met with adverse criticism." Under the head of radium we do not find reference to the spinthariscope of Crookes (p. 950). A new chapter is added on the transplantation of tissues as carried out by Guthrie and others, and one on "parabiosis."

Several of the woodcuts are reversed as they are inserted in the text—e.g., Barker's figures of a pyramidal cell, the neural canal, and brain showing the Rolandic fissure from above as determined by Thane's rule.

The work maintains its high scientific character and will be read with advantage by all candidates preparing for the higher examinations in physiology and desiring to obtain a broad grasp of physiological problems. We cordially commend its perusal also by the practitioner, whose scientific education is now reaching so high a level that he will be able to benefit by the teaching afforded.

---

*An Epitomised Index of Dermatological Literature.* By A. WINKELRIED WILLIAMS, M.B., C.M. Edin. London: H. K. Lewis. 1910. Pp. 275. Price 12*s.* 6*d.* net.

THIS useful book will be welcomed by all who have experienced the tedious difficulties of looking up the literature of past years by a prolonged search through the index pages of the 21 volumes of the *British Journal of Dermatology*. The subtitle—"An Epitome of Volumes I. to XXI., inclusive, of the British Journal of Dermatology"—is the true description of the book, which is not an index to all dermatological literature. The book would have been more useful if it had been possible to add references to the more outstanding dermatological literature in other British medical publications, but the additions and omissions might have led to invidious criticism, and the size of the volume must have been doubled. This drawback is in part overcome by the fact that the book is interleaved throughout, so that the physician who uses it may add his own references culled from any source and also keep his index up to date in future years.

We are surprised not to find the word "Vaccines" in the index, and on turning to "Opsonins" we find no reference to the demonstration given by Sir Almroth Wright and Captain S. R. Douglas, I.M.S., before the Dermatological Society of London in June, 1904, and reported in Volume XVI. of the *British Journal of Dermatology*. Other references for which we have looked have been correct, and we consider that every English-speaking dermatologist will be grateful to Dr. Williams for having performed a task which will save his colleagues so much uncongenial labour.

---

## LIBRARY TABLE.

*Parent and Child: A Treatise on the Moral and Religious Education of Children.* By Sir OLIVER LODGE, D.Sc., F.R.S. London and New York: Funk and Wagnalls Company. 1910. Pp. 73. Price 2*s.* net.—In seven pithily worded chapters dealing respectively with child nature, parental influence, imparting of knowledge, preparation for life, preparation for science, preparation for literature, and preparation for religion, Sir Oliver Lodge brings us back to many true principles that are in danger of being overshadowed, if not entirely cast aside, in our modern State-controlled methods. Preparation of the child for individual life he proclaims the main object of education. The brooding and meditative moods of children should be respected. Stress

is laid on good nursery traditions, training in consideration for others, modesty, helpfulness, reverence for elders, and self-subordination, all points to the neglect of which there is too great a tendency. With regard to fairy-tales, which some would have us ruthlessly discard, while he admits that it is possible to cultivate them to excess, he says that to exclude them and forbid children to hear the old immortal stories—part of the tradition of the race—would be a literary crime. In the inquiring mood children should be supplied with facts; in the imaginative mood with fairy-tales. Some things are better than true. Children must learn that things are not what they seem, and that works of imagination and beauty have a truth of their own which can be felt but not stated. The book can be commended to the thoughtful study of parents and those *in loco parentis*.

*A Text-book of Organic Chemistry.* By A. F. HOLLEMAN, Ph.D., F.R.A. Amst. Edited by A. JAMIESON WALKER, Ph.D. Heidelberg, B.A.; assisted by OWEN E. MOTT, Ph.D. Heidelberg. Third English edition, partly rewritten. London: Chapman and Hall, Limited. New York: Wiley and Sons. 1910. Pp. 599. Price, cloth, $2.50.—We anticipated in a review of the previous edition (THE LANCET, Feb. 15th, 1908) that this work would be widely appreciated. We predicted its success because of the author's gift of discriminating between principles and facts which, on the one hand, are immediately essential to the beginner's grasp of the subject, and those on the other which, at all events in his early studies, only conspire to upset his mental digestion by reason of their richness and intricacy. The new edition shows that many alterations and additions have been made, and a rearrangement of the subject-matter has rendered it necessary to re-number the paragraphs from 199 onwards. We note that the editor, in accordance with a suggestion in the previous review, has introduced the protein classification adopted by the Chemical Society of London and the English Physiological Society. We know of no text-book on the difficult subject of the chemistry of the carbon compounds that is written more clearly than is Professor Holleman's book.

*Treatise on Diseases of the Skin for the Use of Advanced Students and Practitioners.* By HENRY W. STELWAGON, M.D., Ph.D., Professor of Dermatology in the Jefferson Medical College, Philadelphia, &c. Sixth edition, thoroughly revised. With 298 illustrations in the text and 34 full-paged coloured and half-tone plates. London and Philadelphia: W. B. Saunders Company. 1910. Pp. 1195. Price 25*s.* net.—The text-book on diseases of the skin written by Professor Stelwagon occupies such a high position in the opinion of those qualified to judge that any expression of opinion of its value is almost unnecessary, but there may be some medical men who, not having devoted special attention to this branch of medicine, are unacquainted with the work, and therefore it may not be superfluous to say that for all those who desire a thoroughly trustworthy and up-to-date text-book on dermatology we can recommend the volume before us. The rapid appearance of revised editions indicates the great recognition which the work has met with; only eight years have elapsed since the book appeared, and already we welcome the sixth edition. The opportunity of a new edition has enabled the author to omit that which has become obsolete, to rewrite the article on pellagra, and to describe sporotrichosis. We are pleased to see included an account of the uses of carbonic acid snow, as the more the therapeutic agent is employed the more it will be valued.

*Man's Redemption of Man: A Lay Sermon.* By WILLIAM OSLER. London: Constable and Co. 1910.—Professor Osler strikes the keynote of his theme in his opening sentence: "To man there has been published a triple gospel—of his soul, of his goods, of his body." The third engages his present attention. He traces the struggle against disease and pain, those distressing clouds that darken the outlook on the world of life, from its "tap roots" in Hellenic thought to the grand development of preventive medicine in the present day. This lay sermon is thoroughly interesting.

*The Ruins of Fountains Abbey.* By the Rev. A. W. OXFORD, M.A., M.D. Oxon. With illustrations and photographs by J. REYNOLDS TRUELOVE, A.R.I.B.A. London: Henry Frowde. 1910. Pp. viii. + 245. Price 3*s.* 6*d.* net.—This excellent little book is based on the recent investigations of the ruins of Fountains Abbey by Mr. St. John Hope and Mr. Arthur Reeve. As it is written in simple language, with all architectural terms clearly explained, it will commend itself to the general tourist as a handy guide to this lovely Abbey. Moreover, under the guidance of Dr. Oxford the reader will be able to realise something of the magnificence of the old Cistercian monastery, with its church, chapels, guest-houses, infirmary, and kitchens, and to follow the daily life of its inmates. The latter half of the volume contains a history of the Abbey and its rulers, translated from old records. Most medical men are possessed of a scientific or artistic hobby. To a great many the physical sciences most appeal, and we have also amongst us metaphysicians, musicians, and artists. A considerable number find their recreation in archæology, and to these we can commend Dr. Oxford's little volume with confidence. The beautiful illustrations form an important feature of the book, but a list of these illustrations might with advantage have been given as an aid to the student desirous of referring to some architectural detail.

## JOURNALS AND MAGAZINES.

*The Quarterly Journal of Medicine.* Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. IV., No. 14, January, 1911. Oxford: At the Clarendon Press. Subscription price, 25*s.* per annum; single numbers, 8*s.* 6*d.* each net.—The contents of this number are: 1. The Bacteriology of Human Bile, with especial Reference to the Typhoid Carrier Problem, by J. F. Windsor. The contents of the gall-bladder in 103 cases have been examined bacteriologically, and the results are recorded and discussed. The bile proved to be sterile in less than one-fourth of the cases—viz., in 22. The organism most commonly obtained was the bacillus coli, but in four cases bacilli of the typhoid-paratyphoid group were found, although not one of the four was definitely known to have had enteric fever. 2. On Carcinoma Originating in the Suprarenal Medulla in Children, by R. S. Frew. From a study of certain cases observed by himself and of the other cases recorded in the literature, Dr. Frew comes to the conclusion that this condition spreads by the lymphatic system, and that it gives rise to different appearances according to whether the left or right suprarenal is primarily affected, the secondary deposits showing a different distribution in each case. 3. Notes upon Alternation of the Heart, by Thomas Lewis. A brief description is given of a condition of divergent alternation of ventricle and carotid—i.e., one in which a large ventricular contraction corresponds to a small carotid upstroke. 4. The Influence of Certain Factors upon Asphyxial Heart-Block, by Thomas Lewis and B. S. Oppenheimer. 5. On Chylous and Pseudo-chylous Ascites, by R. L. Mackenzie Wallis and H. A. Schölberg, Part II. Two additional cases of pseudo-chylous ascites are described and the characters of the fluid are fully detailed. The distinctions between chylous and pseudo-chylous ascites are

tabulated and an analysis of the recorded cases with a full bibliography is given. 6. On Pneumococcal Peritonitis, by Harold Rischbieth. This paper is based upon a series of 57 cases in children and one adult case. It affords an interesting pathological and clinical study of this condition. 7. A *Résumé* of Some of the Evidence Concerning the Diagnostic and Clinical Value of the Wassermann Reaction, by Hugh Wansey Bayly. 8. Critical Review: Vertigo, by Sydney Scott. A valuable presentation of some of the principal features of vertigo, with a useful bibliography.

*Science Progress in the Twentieth Century.* Editors: H. E. ARMSTRONG, Ph.D., F.R.S., J. BRETLAND FARMER, D.Sc., F.R.S., W. G. FREEMAN, B.Sc., F.L.S. January, 1911. London: John Murray. Price 5*s*.—This quarterly journal of scientific work and thought contains papers on Molecular Architecture, by R. T. Colgate and E. H. Rodd; The Iron Supplies of the World, by J. W. Gregory, D.Sc., F.R.S.; Some Scientific Aspects of the Report of the Canada and West Indies Royal Commission, by Sir Daniel Morris, K.C.M.G.; The Sudden Origin of New Types, by Felix Oswald, D.Sc.; The Great Star Map: Part III., Star Positions, by H. H. Turner, D.Sc., F.R.S.; The Evolution of the Function and Structure of the Fins in Fishes, by H. H. Swinnerton, D.Sc.; The Translocation of Carbohydrates in Plants, Part II., by S. Maugham, B.A.; The Problem of Three Bodies, by F. W. Henkel, B.A.; The Prevention of Malaria, by E. A. Minchin, M.A.; and Recent Advances in High Temperature Measurement, by J. A. Harker, D.Sc., F.R.S. Mr. Minchin's article on malaria is a critical review of Professor Ronald Ross's book, "Prevention of Malaria." He considers Ross's attempt to deal with the problem mathematically hardly calculated to make the process any clearer to the ordinary person unaccustomed to express his thoughts in mathematical formulæ, but useful as a *memoria technica*, by means of which to keep in mind the various factors on which the prevalence of malaria in a given locality depends.

*Jahreskurse für Ärztliche Fortbildung* (*Post-Graduate Review*). A monthly journal. Munich: Lehmann. Price M.16 a year.—The November number is devoted to a consideration of the organs of special sense. Professor L. Bach deals with the eye. Some importance is attached to the influence of light with short wave length in the preservation of the sight. The work of Krusius on trachoma is accepted as proving the causal relation of a protozoon parasite to this disease, and an account is given of the evidence of the transmissibility of it by this means to apes. The problems of secretion and osmosis in relation to the metabolism of the eye are discussed at some length. In the treatment of inflammatory eye affections an important rôle is assigned to the use of both specific and non-specific sera. In particular the anti-pneumococcus serum has great value for the serpiginous ulceration of the cornea. The discussion of the recent methods for the treatment and diagnosis of tuberculous and syphilitic diseases seems a little redundant in this section, as these subjects have been dealt with fully in former numbers of this series. Professor v. Eicken contributes a most interesting article upon the detection of foreign bodies in the air passages and their removal. Brüning's instruments are described and illustrated with some detail. The question as to whether the bronchoscope should be passed through the larynx or by a tracheotomy wound is answered by saying that the latter method is indicated only in cases with much dyspnœa or when the foreign body is large and irregular. Professor W. Kummel writes on the diseases of the ear. His article is devoted almost entirely to the consideration of labyrinthitis. The course and functions of the various nerve tracts of the ear, the special functions and disorders of the cochlea and of the vestibule are each described. The subject of nystagmus in relation to disease of the inner ear is discussed at some length, and Bárány's caloric reaction is given in detail with regard to its method and scope. In conclusion, the non-infectious diseases of the internal ear are considered. ——The December number deals with surgery and allied subjects. Professor Payr devotes himself almost exclusively to the question of skin disinfection. The conclusion is reached that both for accidental wounds and those of an operation the iodine method is by far the best. It is used in the strength of 10 per cent. (this is five times as strong as B.P. tincture which is used in England). No soap and water are used and if any shaving has to be done it is performed with a dry razor. In the treatment of extensive contused wounds it is recommended to excise the whole wounded surface if this can be done within six to ten hours after its infliction. Glass drainage tubes are preferred to all others on account of their smaller liability to become blocked. The treatment of infected wounds by the local application of Peru balsam is strongly recommended. Professor Borchardt deals very fully with the subject of local anæsthesia. After describing the various methods and solutions, the employment of a 2 per cent. solution of novocaine combined with adrenalin is said to be by far the most generally useful method. Practically every region of the body in which the method can be used is described and illustrated. Professor Thiem concludes the volume by discussing the various problems relating to the legal aspect of accidental injuries. Of particular interest are his collected facts about the relation of tumours to mechanical injury and artificial injections. The occurrence of epithelial proliferation after the injection of scarlet red oil, the transmutation of carcinoma cells into those of sarcoma and *vice versâ*, the phenomena of Jensen's mouse tumour are some of the subjects that are shortly reviewed. All parasitic theories of the origin of cancer are dismissed as untenable. With regard to the question of heredity the largest number of collected cases of cancer histories give positive evidence of this inference in only 13 per cent. In these cases the inheritance is twice as often on the mother's as on the father's side. In 329 cases of married cancer patients 3 per cent. produced contact cancer in husband or wife. An interesting series of collected cases is given where there is clear evidence of carcinoma or sarcoma being the direct result of trauma. Körber's figures of the duration of life in different forms of cancer are summarised. From these it appears that the interval between the first symptom and death is shortest in the case of the gall-bladder (4·2 months) and longest in the case of the face (45·6 months).

*The Child: A Monthly Journal devoted to Child Welfare.* Edited by T. N. KELYNACK, M.D. Vict. London: John Bale, Sons, and Danielsson, Limited. Price 2*s*. net.—The February number (the fourth of Vol. I.) contains, like its predecessors, much interesting material. Professor W. H. Perkin, F.R.S., discusses the fireproofing of flannelette and the protection of child life, describing a process that, it is alleged, leaves undiminished the softness, warmth, and cosiness of the material; is non-poisonous; has no injurious action on the skin; and does not, as so many other processes do, come out in the wash. Dr. A. Hugh Thompson urges the formation of school ophthalmic clinics and tabulates the essentials thereof. Dr. D. M. Taylor discusses fatigue in school children, and especially emphasises the difference between ordinary or normal fatigue and the fatigue that has passed into a chronic state, describable as "jading" or "weariness." He discusses the signs and symptoms of the latter, its diagnosis and causation, and summarises the requisites for its prevention, respectively as they affect the teacher, the parent, the school medical officer, and education committees. "Medical Influence in the School" is the title of a paper by

Mr. W. J. Butcher, and this is followed by an interesting discussion on the Punishment of Children, in which almost every point of view is represented severally by Dr. Greville Macdonald, Mrs. H. O. Barnett, Professor E. P. Campagnac, Dr. H. Macnaughton-Jones, Mr. Thistleton Mark, Mrs. Edith Myers and Dr. Charles S. Myers, Miss Charlotte M. Mason, Mr. G. H. Archibald, and the Rev. Dr. A. W. Upcott. There are also a memoir of the Rev. Thomas Guthrie, D.D., by Lord Guthrie; a description of Cheltenham Ladies' College, by Miss E. M. Guinness, the vice-principal; and many other articles on the social economics of child life.

# Reports and Analytical Records
FROM
# THE LANCET LABORATORY.

### AMIDO-AZOTOLUOL MEDICINALE "AGFA."
(CHAS. ZIMMERMANN AND CO., 9 AND 10, ST. MARY-AT-HILL, LONDON, E.C.)

THE active constituent of scarlet R (Sudan red) is amido-azotoluol, scarlet R itself having been used for promoting or stimulating skin formation upon wounds. Amido-azotoluol medicinale "agfa," however, is said to be more efficacious than scarlet R. Its employment in the formation of skin is said to be astonishing. We have examined an ointment containing 8 per cent. of the active agent. We have also received specimens of scarlet red itself and an ointment containing 8 per cent. of this substance. This has also been used with the object of accelerating epithelial formation over granulating wound surfaces and the results are stated to be very satisfactory. They were first obtained by Professor Schmieden of Berlin in 1908.

### TRILACTINE FERMENT No. 1. TRILACTINE FERMENT No. 2.
(W. MARTINDALE, 10, NEW CAVENDISH-STREET, LONDON, W.)

These preparations are worthy of notice as they may be used in the place of sour milk in cases where milk is unsuitable for the patient. Trilactine ferment No. 1 is a pure culture of the Bulgarian bacillus in a liquid medium consisting of malt extract, milk sugar, and peptone bouillon. The No. 2 ferment contains the same bacillus, but with the addition of yeast in the same medium; it is adapted for use in diabetic cases and in obesity. The preparations have the advantage of presenting the active lactic acid bacillus in a relatively small amount of medium, and the lactic acid present can be easily adjusted and reduced if need be to a negligible quantity should the acid be found to lead to undesirable developments. We also examined a sample of trilactine milk, which is a beautifully clean preparation, having a pleasant delicate acid flavour free from bitterness.

### ATHERIUM (WHITE METAL ALLOY).
(PRITT BOWLEY AND CO., 46, FENCHURCH-STREET, LONDON, E.C.)

This is a very remarkable metal, and no doubt will find a wide application in the arts and sciences. Our interest in it is that it has been suggested that it might be suitable for the manufacture of surgical instruments. It has a silvery tone, but the most remarkable thing about it is that it is slightly lighter than aluminium, the specific gravity averaging about 2·5. This remarkable lightness, however, would count for nothing were it not that the alloy is remarkably durable, having a tensile strength of 18 66 tons to the square inch. It is difficult to bend with the fingers a piece of plate one-eighth of an inch thick. In the case of aluminium, of course, that is very readily done. We understand that the alloy makes good sound castings and works well in rolling and turning. Clean screw threads can be cut and it can be soldered, forged, and welded. It is susceptible to the action of acids and certain metallic salts, but resists the tarnishing or corrosion that occur, in the ordinary way. It appears, also, to defy the corrosive action of salt- or sea-water. There is a future for this alloy if its price can be brought within the requirements of practice. It contains for the most part aluminium which is no doubt alloyed with a substance possessing hardening properties.

### PYSHAN POINTS TEA.
(THOMAS CHRISTY AND CO., 4, OLD SWAN-LANE, LONDON, E.C.)

According to the experience gained in THE LANCET Laboratory there is no tea without tannin, the real point of importance being whether the tannin is combined with an equivalent of caffeine, which renders the tannin inactive. "Pyshan Points" tea on analysis proved to contain 12·40 per cent. of caffeine tannate, according to the analysis of a five minutes' infusion (1·25 per cent.). This tannate contained 3 10 parts of caffeine, and 9 30 parts of tannin; the total caffeine in the tea proved to be 3·10 per cent., and the total tannin 9·38 per cent. The caffeine and tannin are present, therefore, in the balanced proportion of 1 to 3, neither being present in the free state in which they may be harmful. The conclusion is that the tea is one of desirable quality from a physiological point of view. It is, further, an economical tea, inasmuch as it is rich in the active principles. We learn that this tea is produced from the leaf edges and young shoots of the plant, all coarse portions being rejected. The flavour of the tea, as might be expected, is agreeably smooth.

### SUPRARENALIN SOLUTION.
(ARMOUR AND CO., ATLANTIC HOUSE, HOLBORN VIADUCT, LONDON, E.C.)

The claims made in regard to the purity of this solution of the active principle of the suprarenal capsule are, according to the examination we made, correct. Suprarenalin solution is prepared from an ash-free active crystalline principle of the suprarenal substance. It is simply the active principle contained in normal saline solution, and is free from objectionable additions.

### STREPTOCOCCUS VACCINE RHEUMATIC FEVER (WELLCOME BRAND).
(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

This vaccine has been obtained from the so-called micrococcus rheumaticus, the presence of this organism having, it is said, been demonstrated in rheumatic lesions and in the blood of rheumatic patients. The vaccine is issued in hermetically sealed phials, containing in the one case 10,000,000 and in the other 50,000,000 organisms. The vaccine has been employed with advantage, it is stated, in persistent relapsing rheumatism.

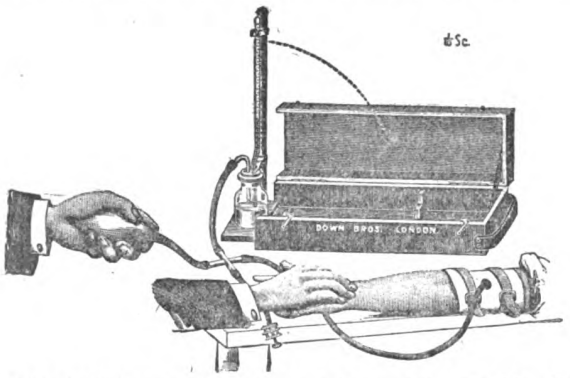
### SEA-WATER PLASMA.
(OPPENHEIMER, SON, AND CO., 179, QUEEN VICTORIA-STREET, LONDON, E.C.)

The supply of sea-water plasma for subcutaneous injections is now being undertaken by the above firm, who have made arrangements to collect at frequent intervals under special conditions the water from the deep North Sea. Precautions are taken in regard to the purity of the water in accordance with the directions laid down by Dr. Robert Simon in Paris. The sea-water plasma is supplied in aseptules of the capacity of 30, 50, and 100 cubic centimetres and in undiluted condition in sterilised bottles of 8 ounces capacity. The treatment appears to have a very favourable effect on nutrition and gives tone to the gastro-intestinal tract. The sea-water, of course, is sterile and isotonic with the blood.

# New Inventions.

## A NEW FORM OF SPHYGMOMANOMETER.

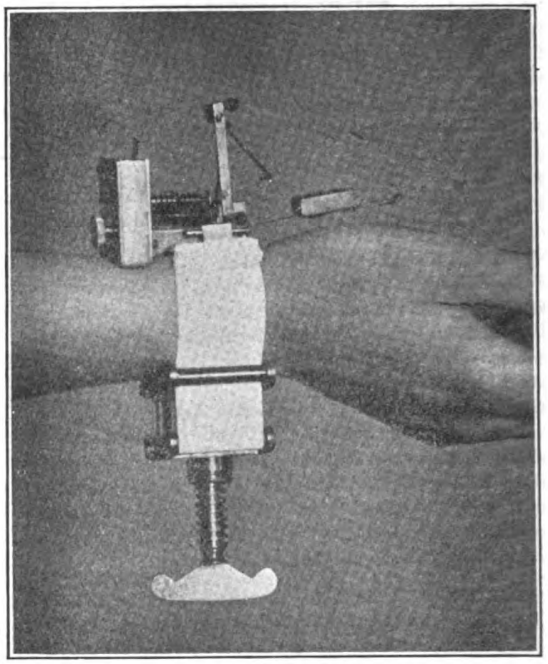
THIS instrument, which has been made at the suggestion of Dr. Herbert French, consists of a vertical mercury manometer connected, as shown in the diagram, with a four-way glass cannula, the other three limbs of which lead respectively to a rubber air-bellows, a broad rubber bag inclosed in canvas for encircling the arm, and a clip for letting out air when required. The principle is similar to that of various other sphygmomanometers devised for measuring the maximum systolic blood pressure. Most instruments of the kind, however, have the disadvantage that until fixed up they are not ready for immediate use, and that unless great care is used the mercury is very apt to become spilled. If the apparatus is carried to a consultation at a distance much time is taken up in packing it so that nothing will go wrong *en route*. In the instrument now described these disadvantages are obviated. The box into



which it fits has one of its narrow sides hinged. To this side the mercury bottle is fixed in such a way that the whole manometer can either stand vertically, as in the illustration, or else be rotated down in the direction indicated by the dotted line and arrow until it lies flat in the box. The length of the glass manometer tube and the amount of mercury in the bottle are so adjusted, that whereas the lower end of the tube is immersed in the mercury when the manometer is vertical the tube leaves the mercury some little time before it reaches the horizontal position. The result of this single adjustment is that the mercury cannot become upset whatever position the apparatus is in. It is something like the ordinary non-spillable ink bottle in this respect. The great advantage of this is that as soon as a reading has been taken the manometer and its attachments can be laid down flat in the box, and the latter can be carried in any position—even upside down—without spilling the mercury. Owing to the hinging of the mercury bottle to the main box no clamp is required to prevent its upsetting. It may also be mentioned that there is a contrivance for making the mercury in the manometer rise or fall smoothly when blood pressure is being measured without wide jumpings and oscillations. The main advantage claimed for Dr. French's sphygmomanometer is that, whilst giving direct readings in millimetres of mercury, it is so constructed as to be equal'y and instantly ready either for transit to a distance or for immediate use upon a patient. Messrs. Down Brothers, Limited, St. Thomas's-street, London, S.E., are the manufacturers.

## AN IMPROVED SPHYGMOGRAPH.

THAT the sphygmograph is somewhat neglected as an instrument of diagnosis and record is largely due to the ineffective and uncertain methods used for attaching it to the patient's wrist. The ordinary attachment may be a buckle, catch, or band, each of which may cause much annoyance to the investigator. The device illustrated occurred to me during a more than usually protracted struggle to get a satisfactory tracing from the soft pulse of a young subject. It consists of an ordinary screw tourniquet fitted with a penny dress band, each end of which projects about 3 inches, and ends in a skirt-clip. No strap is permanently attached to the sphygmograph itself, but when the artery has been felt with the finger in the ordinary way the instrument is put in position, the clips inserted into the holes where the straps are usually fastened, and the screw gradually tightened, when with surprising ease and certainty the lever begins to work. The most accurate gun may be useless unless mounted on a firm and finely adjustable carriage, and the sphygmograph is of greatly increased value and accuracy with firm band and screw adjustment which I have described. The device is strong, instantly attached and detached, and can be carried



without any case, and is already in the possession of many medical practitioners. In conjunction with a good sphygmometer the sphygmograph is of great service, especially in ascertaining whether the action of such drugs as the nitrites is being properly maintained.

Highbury, N. J. ALISON GLOVER, M.D. Cantab., D.P.H.

A WANDSWORTH MORTUARY.—At the conclusion of an inquest held at Wandsworth town hall on Feb. 3rd, Dr. Arthur Dumville Roe, the divisional surgeon of police, complained of the unsatisfactory heating of the local mortuary, in which he had had to conduct the necropsy. The coroner, Mr. John Troutbeck, said he had long thought this mortuary was most unsatisfactory. Considering that doctors had very important public duties to carry out there he thought their comfort ought to be more studied. The condition of this mortuary had long been a public scandal. It offered such a glaring contrast to all other mortuaries in London, for in them doctors could conduct investigations in comparative comfort. The remedy, he thought, lay with the borough council. The jury expressed their agreement with what had been said. The want of accommodation and the general discomfort of the mortuary at Wandsworth have been pointed out on many occasions. Proposals for a new mortuary have been before the borough council more than once, and it is said that a site has been secured. At a comparatively recent meeting of the council there was some question of a difficulty with regard to the settlement of boundaries between two coroners' districts, but it is to be hoped that this will not delay the provision of a more commodious and comfortable place for the performance of post-mortem examinations, and meanwhile it would seem that there ought to be no difficulties in the way of adequately warming the present building.

# THE LANCET.

*LONDON: SATURDAY, FEBRUARY 11, 1911.*

## The Encyclopædia Britannica and its Medical Public.

IT is impossible to withhold a tribute of admiration from the enterprise which has induced the authorities of the Cambridge University Press to undertake the production and issue of the new edition of the Encyclopædia Britannica, the first 14 volumes of which are now before us, even if we have to confess that our sympathy with the undertaking is not quite whole-hearted and that we do not altogether approve either the methods or the extent of the advertisements by which the new issue is being recommended to the public. It is no small achievement to have converted the Encyclopædia from a book which occupied a place of honour upon the shelves of its possessor, which might be looked at with some pardonable pride in its ownership, and which was sometimes referred to in an emergency, into one which, by reason of its more convenient form, may not only be read through from title-page to *finis*, but which appears calculated to furnish reading enough to last the average proprietor for his lifetime. An educated man has been described as one who knows something of everything, and everything of something; and the Encyclopædia is certainly well calculated to assist in the fulfilment of the first clause of the description. Its weakness, of course, lies in the inevitable combination, within the same covers, of knowledge which has passed into a condition of approximate stability with knowledge which is in a condition of perpetual flux, so that the work as a whole, after the lapse of a comparatively short period of time, must of necessity come to rival that historical egg which was pronounced by the curate to be "good in parts," and must also become a snare to the feet of the too confident smatterer who, under its guidance, rashly permits himself to be authoritative in the presence of those who know. It may be doubted, too, whether it does not contain on any subject at once too much information for the requirements of that mythical personage the general reader, and too little for those of the genuine student, so that, on the whole, it may perhaps be described, if we may borrow a line from VICTOR HUGO, as—

"Trop pour la concubine, et trop peu pour l'epouse."

As regards the special requirements of the medical profession, it may be said that the articles of the Encyclopædia contain an enormous amount of important and generally accurate information about the history of medicine and surgery and about the lives of their most distinguished followers, as well as about the courses of epidemics and the characters and causes of disease. That this information is not of a kind, generally speaking, to meet the requirements of the practitioner or to assist him in his daily work is not an objection with any point.. The Encyclopædia necessarily confines itself to broad outlines and to masses of people, while the practitioner chiefly requires to study details in their applications to individuals. A medical officer of health who was preparing a course of lectures on hygiene or sanitation for the instruction of the more intelligent dwellers in his district would find the Encyclopædia an inexhaustible mine of facts and illustrations adapted for his purpose, but for the uses of the practitioner whose locality was invaded by an epidemic it would prove itself of less practical value. It would be likely, nevertheless, to afford opportunities to the members of sanitary committees, or to the local clergy, or even to ladies Bountiful, of cross-examining the medical man with an appearance of knowledge; so that if mumps, for example, were to break out in Little Pedlington it would be quite prudent for the local practitioners to ascertain what the Encyclopædia had to say about that malady, and to be prepared to encounter any criticisms or recommendations which might be founded upon its article. In other respects it hardly appeals more to the medical profession than to any other educated section of the community, and its value as a treasury of knowledge must be estimated by considering how much of the contents of that treasury are likely to be made available by any intending purchaser, either for the gratification of his intellect or for the conduct of his life. The India paper and the flexible cover constitute an enormous advance on all previous editions of the work, adapting it, as they do for the first time, for actual perusal as well as for mere reference; but it is none the less manifest that perusal, to be of any advantage, must be sustained by real interest in the subject matter, and that this, by people in general, can only be either excited or maintained with reference to a limited number of topics. The reader who passes on from the article on CELLINI to that on CELSUS, merely because they are in juxtaposition in the same volume, is hardly likely to derive or to retain important information from either.

On the whole, we are much inclined to think that the class of literature represented by encyclopædias has almost fulfilled its function in the world, and that it is less and less likely to find favour in the future. There will always be room for the slightly expanded dictionary which furnishes detailed explanations of technicalities; and increasing value will be attached, it is reasonable to hope, to such works as the New Oxford Dictionary, and to the help which they afford in the direction of the proper use of words. But there is, we think, an increasing recognition that the great peril of democracy lies in the increasing influence of the smatterer, and that, at a time when the dominion of the world must clearly pass into the hands of those who submit themselves to the guidance of knowledge, the nations who are content with its semblance must of necessity lose their places in the contest. If we are wise we shall recognise in time that the dangers of our being surpassed in the struggle for commerce, or in the race for empire, are mainly dependent upon our neglect of knowledge. Germany for many years has been steadily organising a system of education which, if it does not impart knowledge, at least imparts a respect for it and a complete recognition of its importance, so that the comparatively

untaught are willing to submit themselves to the guidance of those who know; and the difference between the two nations in this respect, conspicuous as it is in many directions, is nowhere more conspicuous than in relation to medicine. The German working man, though the amount of quackery in Germany is extensive, is willing to admit that medical men know more than he about health and disease, and that actuaries know more than he about the possibilities of insurance, and the result is contented acquiescence in a national system of aid in sickness which is being continually improved under the guidance of experts. As yet too many an English working man has never been taught the value of knowledge, and hence thinks himself capable of arriving at a correct decision upon every question which may be submitted to him, while he is systematically encouraged in this belief by those politicians who seek to rise to power wholly by his support. As long as it is a paying policy to flatter the ignorant, and to submit problems which they cannot understand to their decision, so long will there be a manifest temptation to other countries to challenge an imperial or a commercial supremacy which they have long envied, and which we seem no longer solicitous to retain. The spread of knowledge is what is wanted, and the publication of encyclopædias is designed to meet the want. Admittedly one of the dangers of encyclopædias is that they have some tendency to extend the glorification of the smatterer among the partially educated classes, and to induce forgetfulness of the fact that to know something about everything is a definite source of intellectual weakness, unless it be balanced by the complete fulfilment of the other clause of the description. On the other hand, good encyclopædias rightly used are still valuable national possessions. As the accumulations of exact information become unmanageably large the day of encyclopædias may be threatened by dictionaries of special reference, bibliographies, and so on—we think this position has been reached; but for the present we need encyclopædias.

## The Operative Treatment of Cancer of the Rectum.

RECENT conferences on important subjects at the Royal Society of Medicine have proved of great value, for they have shown more clearly than was possible in any other way the diversity of opinion which may exist on the principles of procedure even amongst those who have devoted special attention to a particular branch. In January of this year at two meetings of the Surgical Section there took place on the subject of malignant disease of the rectum and its surgical treatment a discussion which was fully reported in our columns.[1] Operations on the rectum for the removal of cancerous growths have now been practised for many years, but each succeeding decade has seen a marked increase in the extent and complexity of the operations performed and an improvement in the statistical results. Cancer of the rectum, like cancer elsewhere, usually requires an extensive operation for its removal, and at first the tendency was always to limit the operation too much to the neighbourhood of the obvious growth, with the result that secondary appearances of the disease and recurrence of the growth locally frequently occur. At first all attempts made to remove malignant disease of the rectum were practised from the perineum, various tactics being adopted for enlarging the opening by which the growth might be reached. This perineal method was only applicable to tumours situated low down in the bowel, and in many cases, even when a tumour could be readily reached from the anus, the recurrence of the disease locally proved that the amount of bowel excised had not been sufficient. If there was one point more than another brought out by the recent discussion it was the fact that the recurrences of malignant disease of the rectum are frequently long delayed. Not long ago a limit of three years was supposed to prove the sufficiency of the excision, and when those three years had passed the patient and the surgeon congratulated themselves on the success of the operation; but it is now well recognised that recurrence is not at all rare after three years, and even ten years after the operation a return of the disease has been seen. The fact that this late recurrence is purely local in the majority of cases shows clearly that the local operation has been too restricted.

Not long after the operation by the perineal method had become fairly frequent more ambitious procedures suggested themselves. In cases where the growth had been above the reach of the finger from the perineum no radical measures had been undertaken, but the surgeon usually was satisfied with performing a colostomy. In 1885 KRASKE introduced his method of trans-sacral proctectomy, which undoubtedly allowed the surgeon to operate on many cases which are not amenable to the perineal operation. The mortality, which is still ominous, and the numerous modifications of the original operation, show that it has not yet reached an ideal form. Several speakers at the recent discussion spoke highly of this route and stated that they practised it by preference. Undoubtedly it has many great advantages, it gives the surgeon full control over the whole of the true rectum, but it is hardly applicable to a growth involving the pelvic colon. The removal of a rectal growth by an abdominal incision antedated KRASKE'S trans-sacral method by two years, for in 1883 CZERNY made an abdominal incision for the purpose of completing the removal of a rectal tumour which extended too high for the perineal method. Various modifications of the abdominal operation have been practised. It is sometimes performed with, and sometimes without, a perineal incision. Occasionally it is possible after removal of the growth to bring the sigmoid flexure down to the anus while preserving that sphincter. This is an ideal operation so far as the result is concerned in successful cases, but the cases which are truly suited for it are few in number and the mortality is high; yet it found advocates amongst the speakers at the Royal Society of Medicine, and it is possible that in the future means may be found for reducing the death-rate from it. In most cases when the abdominal route is adopted all that can be done is to leave an abdominal anus, and the discomfort from this cause is generally less under modern

[1] THE LANCET, Jan. 14th (p. 100) and 28th (p 230), 1911.

methods than used to be the case, and it is at least debatable which is the more convenient site for an artificial anus—the sacral region or the abdomen.

Another point in regard to which divers opinions were expressed was the desirability of performing a preliminary colostomy before proceeding to the excision of the growth. Undoubtedly in favour of a preliminary colostomy are the comparative freedom from sepsis which it ensures, the more speedy healing of the wound, and the greater comfort to the patient. On the other hand, a colostomy opening entails an anchoring of the sigmoid in the inguinal region, and this is disadvantageous if an attempt is to be made to bring down the upper portion of the bowel to the anal opening. The experience of all those who have been accustomed to practise a preliminary colostomy will be in agreement as to its great value and its simplification of nearly all operations for the removal of a growth of the rectum, and, moreover, the incision of the abdominal wall necessary for the formation of a colostomy enables the surgeon to examine the glands of the mesocolon and the liver itself, so as to know whether secondary infection has occurred—for it needs no saying that, if extensive involvement of the mesocolic glands or any infection of the liver is present, an operation for excision of the malignant growth will be contra-indicated. On the whole, the majority of surgeons will agree that a colostomy performed in advance of any operation for the removal of the growth of the rectum is of value. It is clear that, if the surgeon, after excision of a rectal growth by the abdominal route, does not intend to reconstitute the continuity of the bowel but designs to make an abdominal anus, a preliminary colostomy is uncalled for.

There was unanimity amongst the speakers as to the undesirability of attempting the removal of rectal growths which have extended too far; so long as the growth is confined to the rectum the possibility of removing it completely is great, but if it has spread elsewhere no operation for removal is likely to prove of permanent value. In the very old, too, a radical operation is undesirable, and in all these cases the value of a palliative colostomy was acknowledged by several speakers. When the irritation of the fæces is prevented the progress of the growth is often extremely slow and several years of fair comfort may be enjoyed. Some twelve surgeons took part in the discussion, and their names include most of those London surgeons who have specially worked at diseases of the rectum, and therefore we are justified in accepting the opinions expressed at these meetings as indicative of modern opinion in London. Practically all agree that the perineal route is hardly ever to be employed; most condemned it utterly. Opinions were divided on the question of the value of the trans-sacral operation. Some preferred it in nearly all cases, while others believed the abdominal route to be the better. All would assent to the statement that, if the sigmoid could be brought down to the anus, with the preservation of that sphincter, after complete and adequate removal of the malignant growth, the result would be ideal, provided that the mortality could be kept low; but most of the speakers doubted the possibility of combining this method of operation with sufficient removal of infective tissues, while to others the main obstacle appeared to be the heavy mortality with which it was accompanied. So for the present the matter must be left, but we are inclined to think that in a not far distant future some modifications of operative procedures will result in a greater unanimity in the choice of the site of operation. In the meanwhile we congratulate the Surgical Section of the Royal Society of Medicine on this interesting and valuable discussion of an important question.

## Health and the Hotel Interest Abroad.

THERE is a warfare which is not military, preceded by no diplomatic overtures or formal declaration of hostilities, resulting in no death-roll or list of wounded, in no exchange of prisoners or cession of territory, mitigated on the field of battle by no Geneva Convention—a warfare, however, none the less real, embittered, and relentless because, from inability of the opposing champions to meet in physical combat, it stops short of personal violence. Its seat is the southern region of Europe, principally where this abuts on the Mediterranean, its scenes of hottest action "winter cities" or "sun traps" frequented by the foreign or paying guest, and the belligerents the hotels and their management, French or Swiss on the one part and Italian on the other. The warfare thus waged is at its height in the so-called tourist season—that is, from the late autumn to the advanced spring—and the "weapons of precision" (rather less than more precise) in favour with the combatants, are those of reciprocal misrepresentation and disparagement, striking at nothing which can discredit the opponent or deflect from him the custom so dear to both.

The season now well on its way has witnessed an unusually keen succession of such encounters, and the advantage, strategic and other, has hitherto been on the side of the French and Swiss, as against the Italian belligerent. This latter from the late autumn has been fighting under every conceivable difficulty, of which its antagonists have been all too prompt to avail themselves, and the tide of battle has driven it, baffled and dispirited, well-nigh to its last entrenchment. The cholera scare, hardly overcome in October last, continued an effective weapon against it till well on into the winter, and even now has still strength enough to keep the Sicilian and Neapolitan hotels all but empty. Though never approaching the epidemic stage, and numbering its victims only among the poorest of the proletariat and of these but a very few, the "Asiatic invader" was credited with a diffusion and a virulence that sufficed to keep the northern world at bay or to confine it to the Swiss slopes of the watershed and the French Riviera. The hotels in that region throve abundantly on the well-maintained fiction, some of them boldly inscribing on their *menus* at *table d'hôte* a warning against any sojourn, however short, in Italy as fraught with danger to invalid and robust alike. Now that the cholera has ceased to play the deterrent, other weapons from the sanitary *armamentarium* have been pressed into the service; and after an ominous hint as to small-pox, with a side-glance at the dangers from earthquake, perennial

as these are held to be in Italy, the influenza is, in the day now passing, brought within range, and, truth to tell, has been doing effective execution against Italian interests, particularly in Rome and Florence. The last scene of an attempted scare in the transalpine cause is that great *entrepôt* of tourist traffic Milan, insomuch that a counter demonstration has had to be issued by its "Ufficio Municipale d'Igiene" setting forth the exceptionally sound conditions of the public health both in city and suburb. The Regio Commissario has published statistics showing the absolute immunity of the Lombard capital, not only from cholera, but from all epidemic disease of an infective type, and its leading journals, in giving voice to his conclusions, comment with well-warranted indignation on the fictions put in circulation, to the prejudice of the city, by interested parties. The Regio Commissario, the Commendatore GALLOTTI, remarks on the difficulty of antagonising such malicious reports, propagated by agencies other than journalistic, against the fair fame of a great centre conspicuous for the intelligence, the energy, and the efficient service of its board of hygiene. Milan, it is true, has special reason to complain that its sanitary record has not always a counterpart in its sister centres, and that the inefficiency of other hygienic offices plays into the hands of the critic, none too scrupulous in discriminating between one Italian city and another. It has to suffer, in other words, for the shortcomings revealed in Sicilian and Neapolitan health resorts, creating, if not justifying, as these do, a sinister impression as to the general sanitation of the kingdom.

There are two Italies, as the statistics of the last few years have put in evidence—the Italy of the north, intelligent, enterprising, and eager to fall into line with contemporary progress; and the Italy of the southern mainland and the islands, where the proportion of the *analfabeti* is some 70 per cent., and where all the administration, hygienic and other, is on a similar plane. Surprise visits in those regions on the part of the KING, impartial reports by leading clinicians and consultants deputed *ad hoc*, have revealed a state of backwardness not only discreditable to the local authorities but providing an all too welcome handle to the detractor whose business it is to deter the invalid, the valetudinarian, and the sun-seeking visitor from Italian resorts. It is in this direction that Italy has to set her house in order, stimulated as she ought to be by the promotion of the grave interests she has at stake and by the conviction, now dawning upon her, that to cope on equal terms with her rivals on the Riviera and across the Alps she must disarm the power to criticise her and make all warfare of calumny effective against none but those by whom it is malignantly waged.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Feb. 6th, the Duke of Northumberland, the President, being in the chair. Among the newly elected members were Dr. W. S. Colman, Dr. A. H. Levy, and Dr. N. Raw. The special thanks of the members were returned to Dr. J. Y. Buchanan for his donation of £100 to the fund for the promotion of experimental research at low temperatures.

## LIBRARIES AND LIBRARIANS.

IN the winter time our thoughts seem naturally to turn to libraries, not only for instruction, but also for recreation and consolation. There can be little doubt that winter darkness and winter weather have an influence on book reading, and that books offer us literally *lucem in tenebris*. It is on record that in 596 A.D. St. Augustine brought nine volumes into England, which formed the nucleus of the first English library. Since that time we owe much to the monasteries for preserving valuable books and papers. Now, however, as Mr. Victor G. Plarr, the librarian of the Royal College of Surgeons of England, reminds us, in an interesting paper read before the Medical Library Association last year, and published in the *Dublin Journal of Medical Science* for November last, their place is occupied by *M. le Bibliothécaire*, the curator of the library. *Monsieur* is a worker in the hinterland of literature, whose work none the less shall endure and blaze the trail and prepare the way for the literary immigrants of the future, if conscientiously done; and no librarian can be a true *bibliothécaire* without being conscientious. His task it is to excavate the covered plains of literature and to display their hidden treasures with critical acumen, so grouped and classified as to be convenient of study from whatever point of view the student may approach a given subject. Mr. Plarr rightly points out that "the making of a title is, indeed, a small art of itself. ..... A book title should, of course, have no dubious element about it, but should be absolutely definite." Yet of many books it may truly be said that their titles are given them to conceal their contents. Whence, as Mr. Plarr points out, *M. le Bibliothécaire* must possess many sterling qualities—method, industry, and sound judgment; he should be a sound logician, something of a grammarian, a rhetorician, and a geographer, as well as a polyglot linguist, and particularly a Latinist, a man acquainted with the movements of science, a man of letters, a man of the world, perhaps a traveller, and of necessity a wide reader. But since he has to deal not only with books but also with people, he must be urbane and merciful to the ignorant, able to conceal his amusement at the naïveté of many who consult him, and superior to the weakness of making less instructed persons "feel small." The need of these qualities Mr. Plarr emphasises by instance and reminiscence. For example, he himself was once tested by being asked by a certain eminent librarian to classify at sight a work entitled "De Cornutis." It seemed catchy and incomprehensible, and he perspiringly replied, "'De Cornutis, concerning horned beasts." To which the eminent librarian very grimly replied: "Yes, they are horned beasts." In the jargon of the ancient satirists, then a *terra incognita* to the youthful librarian, *cornuti* are cuckolds. Mr. Plarr adds: "I question if many would pick up this piece of information at any time during their earthly pilgrimage." Yet readers of Shakespeare who are to be found in circles quite outside of professional scholars will surely recall the poet's references to "horns," when he speaks of a "horn-maker," meaning a maker of cuckolds, alluding to the imaginary antlers or projections on the temples of the cuckold. Mr. Plarr bewails the fact that a catalogue in the long run "tends to become a queer, rather pathetic amalgam of old ideas and modes of thought." Nosology is in a constant state of flux, and terms survive in

nomenclature after the conception that prompted them is exploded, or swallowed up in a more comprehensive grasp of the subject. What is most wanted in a classified catalogue is elasticity, a means of grouping correlated books in close proximity, with a mode of cataloguing them that shall be independent of changes in nomenclature. This is the aim of the decimal numerical system of classification so extensively used in America and on the Continent of Europe, and we should like to know Mr. Plarr's views on the point. With regard to the card system of indexing Mr. Plarr makes the very practical suggestion that when an "author card" involves many subject cards as cross references a complete list of these subject cards should appear on the back of the author card, so that in case the book is for any reason withdrawn all the references to it can be withdrawn also. Those who have done much card indexing will entirely endorse the statement of the author, that "sometimes one is in a more meticulous mood than at others," and prone unduly to multiply subject headings or to write out titles more at length than usual.

## THE WEATHER OF JANUARY.

AFTER adding about 12 more wet days to the long period of rain that began with November, January became very dry in almost all parts of England and Scotland, while the weather improved considerably in Ireland also. A large portion of England had no rain or, at the most, a very slight fall on one or two occasions, after the 10th or 11th, and as the amounts measured before those dates were not generally large, in spite of the frequent falls, the aggregate quantity for the month was much less than the January average. In several districts of England there was less than an inch, or not as much as 50 per cent. of the average, and a similar shortage was recorded in some Scottish districts and in the south-west of Ireland. In London (Westminster) and also at the Kew Observatory the total amount was less than 1·2 inches, or 65 per cent. of the normal, and except on the 22nd, every day after the 12th was rainless. Although so many days were rainless, however, the sky was so often charged with dense cloud that the records of sunshine were not particularly large over the kingdom as a whole. A few spots, mostly in the south, were fortunate enough to see the sun for an appreciable number of hours longer than usual during the chief month of winter, but generally the divergence from the average was not great, and it was not everywhere on the right side. In Central London, as represented by Westminster, there were 21 hours against an average of 19 hours, and in the City, at Bunhill-row, there were no more than 11 hours, a deficit of four hours. The suburbs, as is invariably the case in winter, and generally at all seasons of the year, were much more sunny. At Kew Observatory the sun shone for 49 hours, or five hours more than the average, while at Hampstead the record was as high as 59 hours. Greenwich caught 14 more hours than Westminster, but its total of 35 hours was six hours short of the normal. Along the south coast of England the figure was agreeably higher, 70 hours being rather the rule than the exception, and some resorts recording about 80 hours. The temperature of the month, considered as a whole, was not very different from the normal, and a normal January in this country cannot properly be regarded as cold. Frost was seldom recorded by the thermometer in the screen, and many nights passed without frost being registered even by the instruments exposed on the grass. There was only one brief touch of real winter, occurring about the middle of the month, when the screened thermometers in the eastern districts of England descended to below 25°, and the maximum readings of the day were not far removed from the freezing point. In London (St. James's Park) the screened thermometer fell to below 32° on no more than five nights, the lowest figure being 26° on the last night of the month, but at Kew Observatory there were eight nights with more or less frost, the lowest value being 22° on the 16th, and at Hampstead the number of frosts was as many as 11, and like Kew, the lowest reading in the screen was 22°. This reading was recorded, however, on the last night, not on the same date as that at Kew. At the Scilly Islands no frost was registered except by the grass thermometers, and hardly any occurred in the Channel Islands and on the extreme south-west coasts of England and Ireland. Over the kingdom generally the month owed its comparatively high temperature rather to the mildness of the nights than to the warmth of the days. Maximum readings of 50° and above were rare, and on several afternoons the thermometer failed to rise above the normal, and on some remained below it. In St. James's Park a maximum of 50° or a trifle higher was recorded on four days, but on five days there was no reading so high as 40°. The climatic conditions on the Riviera were generally very fine and sunny, although on a few occasions the wind was both cold and rough. As a rule the shade warmth of the afternoons was about 50°, or between 50° and 55°, but on a small percentage of the days the thermometer stopped its upward march before reaching 50°. Round about the 20th the weather was that of genial spring for a time, the shade temperature rising to between 60° and 64°. The nights were not cold for January, although frost was often recorded on the ground, and occasionally in the screen. Italy was colder as well as less sunny, and experienced more rain. The month as a whole, however, was by no means unfavourable for visitors from the colder countries, and in the extreme south of the kingdom, and also in the adjacent islands of Sicily and Malta, the temperature was fairly high. At Biarritz the conditions were more variable. A few days occasionally were bright and warm, and some were mild without the brightness, but the weather generally was cold and unsettled. Frost was frequently recorded, and many of the afternoons were colder than in the south and south-west of these islands. There was, however, little rain after the first fortnight. In Switzerland and throughout nearly the whole of Central Europe the weather was generally very suitable for the winter sports. A fresh layer of snow usually accompanied the few occasions when the thermometer left its frosty winter level, but during the greater part of the month the weather was very cold and dry and often extremely bright. In Bavaria the frost was very intense at times, the sheltered thermometer falling to close upon zero Fahrenheit, and remaining much below 32° throughout the day.

## THE TREATMENT OF SLEEPING SICKNESS.

DURING the three years from June, 1907, to June, 1910, 776 cases of sleeping sickness were treated in two camps in German East Africa at Kigarama and Kishanye. The results are stated by Staff-Surgeon Ullrich in a paper that appeared in January in the *Archiv für Schiffs- und Tropen-Hygiene*.[1] In 650 of these 776 (84 per cent.) diagnosis was confirmed by the finding of the trypanosomes. During the three years 25 per cent. of the cases advanced towards recovery, but as Staff-Surgeon Ullrich does not consider any case cured unless for two years free from trypanosomes, it will surprise and discourage no one that in three years only one person was discharged cured. Another was, however, just on the point of discharge. Cases are divided into three classes: the first make no complaint of illness but have enlarged glands and trypanosomes in the blood; the second

[1] Band xv., Heft 2, p. 41.

class are more advanced and know they are ill; the third are wasting and manifest nervous changes and alterations in gait. Prognosis, according to the report, is hopeful in the first stage; recovery may possibly occur in the second, and has even in the third stage been reported. In December, 1908, 406 cases in good general health and free from trypanosomes were taken off all treatment. Their blood was examined at intervals, and if trypanosomes reappeared treatment was resumed. One and a half years later, at the end of the period, 47 still remained free; 46 of them had shown trypanosomes when admitted. As to treatment, atoxyl has been most used and seems most trusted. Arsacetin is not considered safer or better, nor does arseno-phenylglycin receive more praise, as its toxic phenomena (skin eruptions, wasting, paralyses) are prominent. Arsenic was used but severely disturbed digestion. Antimony had no effect on the trypanosomes. Mercury did not assist the action of atoxyl whether given by injection or inunction. Atoxyl was given by injection every fortnight for five or six months, and was then intermitted for three months, to avoid the damage to the eye which may follow the use of all these organic arsenic compounds. The first evidence in the cases under notice of such damage was a peripheral contraction of the field of vision. As atoxyl was used for all these cases at first, it could not be decided whether damage to the eye during the administration of arsacetin and arsenophenylglycin was due to these drugs themselves or to the preceding atoxyl. Cases that have once lost their trypanosomes and relapse have a most unsatisfactory prognosis, and are not saved by increasing the previously effective doses.

## THE DANGERS OF PARTURITION IN ELDERLY PRIMIPARÆ.

THE question as to whether an elderly primipara incurs any extra danger in childbed on account of her age is one which has been much debated by obstetric writers from the very earliest times. It has recently been submitted for our consideration by a medical correspondent. It would seem only natural that the greater rigidity of the soft parts which is supposed to exist in the older woman, and the partial ankylosis of the coccyx which may also be present, undoubtedly would increase the difficulty and the duration of the labour. Among the older writers—for example, Puzos, Smellie, Deventer, and Mauriceau—this view of the matter was generally accepted, and it was regarded as a true explanation of the assumed increased difficulty of parturition in women beyond their first youth until it was challenged by Madame Lachapelle. Her clinical experience did not tally with the current teaching on this matter, and as she pointed out, while it was quite true that difficult and prolonged labours occurred not infrequently in elderly women, she did not think that they occurred relatively more frequently in them than in women of a younger age. Her view of the matter found support from Cazeaux and Depaul; but, on the other hand, it was opposed as incorrect by Dubois, Wigand, Michaelis, and Naegele. In an endeavour to settle the question an appeal was made to statistics, and papers were published by various writers in favour of one or other side of the question. The figures collected by Cohnstein and Ahlfeld, and quoted by Varnier, seemed to show that not only was labour in elderly primiparæ attended with increased danger to the mothers and the children, but the duration of the labour was increased considerably and the frequency of bad tears of the soft parts was much greater. The supporters of Madame Lachapelle's view pointed out, however, that these conclusions did not settle the matter, since the investigators had not taken sufficient care to compare precisely similar facts, and in a considerable number of their cases there was either a contracted pelvis present or the labour was a complicated one. But statistics collected with greater care, so as to eliminate such errors, tended to confirm the views of those who maintained that with an increase of age is associated an increase of danger, and there seems no doubt that such a conclusion represents the truth of the matter. On the suggestion of the late Professor Varnier, his pupil Dubé carried out an investigation on the subject, taking care to include in his tables only cases of perfectly normal labour. His figures show that while in the great majority of the labours there is no difference in the average duration at all at the various ages, yet in the small minority of the cases in which labour is unduly prolonged the number of elderly primiparæ exceeds that of young primiparæ by some 10 per cent.; and the prolongation of the labour affects both the first and the second stage. If the frequency with which the labours required artificial termination with the forceps is considered, there is a more striking difference. Thus, while among the young primiparæ the forceps rate was only 1·6 per cent., it rose to no less than 25 per cent. among the elderly primiparæ. These figures are the more instructive since in every other respect the labours were normal, the children were of average size, and there was no evidence of any undue rigidity of the bony outlet of the pelvis. The explanation, therefore, of the increased length of the labours in the minority would seem to lie partly in some extra rigidity of the soft parts and partly in some failure of the contractile power of the uterine muscle possibly associated, as Varnier suggested, with the presence of minute fibroid nodules in the uterine walls not recognisable by ordinary palpation. Not only is there then in a small percentage of elderly primiparæ a somewhat excessive prolongation of labour and an increased need for delivery by forceps, but this is associated with a definite increase in the fœtal mortality, since in Dubé's cases it amounted to 5 per cent. in the elderly primiparæ as contrasted with a fœtal mortality of only 1·32 per cent. among the young primiparæ.

## THE SALE OF POISONS.

THE annual report of the Registrar under the Pharmacy Acts, which was received and adopted at the February meeting of the council of the Pharmaceutical Society, contains some interesting details of the work done in 1910 in connexion with the administration of the penal provisions of the law relating to the sale of poisons. During the year 1836 cases of alleged infringement of the Acts were investigated and legal proceedings were instituted in 273 cases. Compared with previous years the work of the law department was exceptionally heavy; in 1909 the number of cases investigated was 1360 and the number of cases in which proceedings were instituted was 155, while in 1908 the number of alleged infringements which were made the subject of inquiry was less than one-fourth the number investigated in 1910. The heavy increase in the work accomplished by the department is to a large extent due to the fact that a new class of poison sellers was created by the operation of the Poisons and Pharmacy Act, 1908, by which local authorities were empowered to grant licences to unqualified shopkeepers to sell poisonous insecticides, weed killers, sheep dips, and other preparations of a like nature. This extension of the sources of distribution of poisonous compounds naturally increases the danger which is always attendant on the traffic in toxic substances, the more especially as these new poison sellers are drawn from a class of retail traders whose training has not impressed upon them the necessity of scrupulously complying with such formalities as it is proper to observe when selling poisons. For instance, some of

the cases which have been investigated reveal the fact that seedsmen and others in selling compounds containing nicotine have neglected to label the bottles with their names and addresses. The number of seedsmen and ironmongers against whom proceedings were instituted on account of various irregularities last year was 71, while in 39 other cases the offences were alleged against assistants to seedsmen. The newly created poison sellers, however, are by no means the only offenders, for the list of cases shows that in 78 cases proceedings were instituted against drug-store proprietors, and in 31 cases penalties were claimed from registered pharmacists or their unqualified assistants. In three instances the defendants were unqualified assistants to medical practitioners, and in all three cases the offence alleged to have been committed was the sale of poison. In one instance the summons was dismissed, but in the other two cases, which were heard in Glasgow, convictions were obtained. Some interesting figures are also contained in that part of the report which deals with the Register and the examination. Last year the number of candidates for the qualifying examination was 1037, of whom 407 were successful, the percentage of failures being rather lower than usual. The number of names on the Register is 16,292, an increase of 36 on the previous Register.

## HÆMOLYTIC JAUNDICE IN SECONDARY SYPHILIS.

FROM time to time cases have been recorded of jaundice in secondary syphilis. The jaundice has been regarded as a rare complication of the disease without considering the question whether it was mere coincidence and due to some intestinal disturbance. For a more minute investigation of the subject we are indebted to French observers, as, indeed, we are for a more accurate knowledge of the pathology of jaundice in general. At a meeting of the Société Médicale des Hôpitaux of Paris on Dec. 2nd M. de Beurmann, M. Bith, and M. Cain reported a case of hæmolytic jaundice in secondary syphilis. They pointed out that ordinary catarrhal jaundice must have often occurred in secondary syphilis as the result of digestive troubles caused by the disease or its treatment. This would present the usual characters of obstructive jaundice. In the case now reported, on the contrary, the jaundice had all the characters of hæmolytic acholuric icterus. It was due to an alteration in the red blood corpuscles. Two similar cases have been previously reported by Professor Gaucher and M. Giroux, and these hæmolytic characters seem to show the causal connexion between the jaundice and the syphilis. A girl, aged 19 years, was admitted into the Saint Louis Hospital with jaundice and a syphilitic roseola on Nov. 2nd, 1910. There was no trace of a primary lesion, but characteristic inguinal and submaxillary adenopathy was present. On the neck were papulo-squamous lesions. Jaundice appeared three weeks before admission, and the roseola a week later. No gastro-intestinal trouble preceded the jaundice, and there was no family history of jaundice. On admission there was marked jaundice of the skin and mucous membranes, but the urine was not darkened and did not give the reaction for biliary pigment, and the stools were not decolourised. The liver was not enlarged. The spleen was not palpable, but was so much enlarged that the splenic dulness measured 4½ inches in the axillary line and 3 inches transversely. An intramuscular injection of a third of a grain of biniodide of mercury was given daily from Nov. 6th. On the 10th the jaundice was much diminished, and the roseola was decidedly paler, but the size of the spleen had not diminished. On the 18th the jaundice and the roseola had almost disappeared, and the splenic dulness was reduced to 2¼ inches in the axillary line and 1½ inches transversely. On the 25th there remained only icterus of the conjunctivæ, and the spleen was no longer perceptible to percussion. There were some vulvar and anal mucous patches, which disappeared three days later after cauterisation with silver nitrate. On Nov. 4th blood was withdrawn from a vein for examination. It coagulated normally, but the serum was of a deep yellow colour, the presence of bile pigments was proved by Gmelin's reaction, and there were also traces of urobilin. The red corpuscles numbered 3,570,000 and the white 30,000, and the hæmoglobin was 90 per cent. A differential count showed 74 per cent. of polynuclear neutrophiles, 6 per cent. of polynuclear eosinophiles, 2 per cent. of large mononuclears, and 18 per cent. of medium mononuclears and lymphocytes. There were about 10 to 15 per cent. of granular red corpuscles, of which some were polychromatophile. The resistance of the red corpuscles to hæmolysis (*résistance globulaire*) when separated from the plasma and placed in normal saline solution was found to be subnormal. On Nov. 26th the number of red corpuscles had risen to 4,500,000, the "globular resistance" was normal, there were few granular red corpuscles, none of which were polychromatophile, and the serum was only faintly tinged with bile. The case corresponded in every particular to the hæmolytic jaundice studied by Chauffard, Widal, and their pupils. There was acholuric icterus without alteration in the urine or fæces, but with biliary pigment in the serum. The slight anæmia, diminished "globular resistance," granular red corpuscles, and splenomegaly completed the picture. Obstructive jaundice was thus excluded. This form of jaundice (with bile in the urine and decolouration of the fæces) has been described in secondary syphilis by Gubler, who attributed it to "roseola of the biliary passages." In the present case the jaundice appeared with the secondary eruption and also yielded with it to the mercurial treatment, as did also the splenomegaly. It is noteworthy that there were no hepatic symptoms and that the liver appeared to play no part in the production of the jaundice. This case is similar to those described by Gaucher and Giroux referred to above. In them there was also slight anæmia, the red corpuscles numbering respectively 3,800,000 and 3,400,000.

## A SIMPLE METHOD OF VIEWING SKIAGRAMS STEREOSCOPICALLY.

IN the *New York Medical Journal* of Jan. 14th Dr. M. Girsdansky has described a simple method of viewing skiagrams stereoscopically. Assuming that the object is of such size as to be capable of being skiagraphed twice on the same plate he places it over one half of the plate and protects the other half with a sheet of lead and takes a skiagram. He then reverses the procedure, placing the lead over the already exposed part and the object over the unexposed part, carefully maintaining a position as symmetrical as possible to the source of the rays and the object's former position. When the plate is developed it shows a picture which resembles one taken with a stereoscopic camera, but it differs from the latter in that opposite the right eye is the picture which would be seen with the left eye in the stereoscope and opposite the left eye is the picture which would be seen with the right. The skiagram is placed at a convenient distance from the eye and a fenestrated cardboard with an aperture in the centre about equal in size to one of the pictures is interposed at such a distance and in such a position that the right picture is entirely and solely visible to the left eye, and the left picture similarly visible to the right eye. If both eyes are focussed upon the cardboard the skiagram appears at the window as an image in three dimensions. Some difficulty may be experienced in focussing the eyes on the empty window. This may be overcome by fastening one or more microscopic slides to the

window by means of adhesive plaster, so as to completely or partially cover it. The glass acts as a "target" on which the eyes can be focussed with greater ease than upon the empty window, but after a little practice the glass can be discarded. This method has several advantages. It is much simpler than the ordinary method of X ray stereoscopy by means of two mirrors at right angles to one another. Skiagrams printed in books or journals can be viewed without removing the pages—i.e., without mutilating the book or journal. Skiagrams prepared by this method can be thrown upon a screen, and no matter how many times enlarged can still be viewed in three dimensions. It is noteworthy that the stereoscopic image appears smaller than each of the skiagrams which compose it. Obviously the reason is that while the image appears to be situated at the window where the axes of vision converge, the retinal images are formed by the more distant skiagrams. These images are therefore smaller than if the skiagrams were at the distance of the window and the object appears to be proportionally smaller.

## RESEARCHES ON THE CENTRAL NERVOUS SYSTEM OF INFANTS BORN OF DISEASED PARENTS.

HEREDITY and its problems are more than ever *à l'ordre du jour*. On all sides the attack is being pushed home with ardour by the statistician, the Mendelian, and the pathologist. There is a growing feeling that in the matter of heredity hypotheses have been vaunted just a little at the expense of facts, and while the serviceableness of the former need never be deprecated a wide observation and collation of mere facts is urgently called for. No word is more familiar, or more useful let us say, in the study of heredity than "predisposition," yet it is a current conception whose basis on accepted facts is partly conjectural. To express "predisposition" in organic terms is the laudable aim of Dr. Catola, of Professor Tanzi's Nervous and Mental Clinic in Florence, whose article will be found in the *Revue de Médecine* for September of last year. Dr. Catola's method is to examine the central nervous system of infants born of parents suffering from some disease, and to determine in what way, if any, it may show a departure from the normal. He is content to record facts, for deductions, in view of the paucity of the former, would be premature. A great deal of work has already been done on the retarding effect of different maternal toxi-infections on the development of the fœtus, and on the causal relation between given intoxications and diseases in the parent or parents and the appearance in their children of a whole series of morbid conditions, such as epilepsy, hysteria, deaf-mutism, idiocy, &c., or of more or less marked teratological changes. But it is desirable to examine minutely the nervous systems of infants dying at birth or soon after born of mothers affected with some disease of a chronic nature, to discover whether any pathological changes can even at that early stage be recognised. Even admitting that present histological technique is not perfected and that the complexity of the factors involved renders interpretation of any alterations supremely difficult, Dr. Catola is perhaps right in his contention that by attacking the problem of hereditary, familial, and congenital diseases along these lines we may begin slowly to establish a basis of ascertained facts to serve to illustrate the meaning of "predisposition." In this first communication he has occupied himself solely with cases of infants dying at birth whose mothers have been suffering from chronic disease; the spinal cord only, however, has been subjected to investigation. His results may be summarised as follows: 1. Mother suffering from severe Bright's disease: premature birth at 6½ months. Central canal of spinal cord of infant not closed below the lumbar enlargement. 2. Mother syphilitic: premature birth at 8 months. An immense number of granular fatty pseudo-cells (masses of cell-like fatty débris staining with osmic acid) especially in the posterior columns. 3. Mother tuberculous: premature birth at 7½ months. Complete absence of myelinisation in the direct pyramidal tracts (normally myelinated at the sixth month of intra-uterine life). 4. Mother syphilitic: full-time child. Masses of fatty granular cell-like bodies in the middle of the crossed pyramidal tracts (Bechterew's *faisceau intermédiaire*). 5. Mother syphilitic: premature birth at 7½ months; liver full of spirochætæ. Fatty degeneration of intraspinal anterior roots; myelinisation of tract of Burdach normal; of tract of Goll, greatly retarded; slight lymphocytic infiltration of pia mater anteriorly. 6. Mother suffering from pernicious anæmia: premature birth at 7 months. Immense number of pseudo-cells in the posterior columns; fatty débris in the posterior roots where they pass the pia mater; numerous small hæmorrhages both in grey and in white matter; defective myelinisation in cervical and lumbo-sacral cord. 7. Mother tuberculous: premature birth at 6 months. Myelinisation in dorsal cord almost entirely wanting. Masses of cells in the posterior root ganglia. 8. Mother suffering from nephritis: eclampsia; premature confinement at seventh month. Degeneration of anterior spinal roots in their intraspinal part; intense chromophilia of the anterior horn cells; small disseminated hæmorrhages; large colonies of cells in the posterior root ganglia. It would, of course, be inadvisable to speculate on the possible significance of all or any of these pathological changes; antenatal pathology of the central nervous system is almost a *terra incognita*. Dr. Catola confines himself to the following conclusion: "Different morbid conditions in the maternal parent may be associated with defects of development and slight lesions in the central nervous system of the children such as may, in the case of the latter surviving, play a certain rôle in the mechanism of morbid predisposition."

## AN EXTEMPORISED TUBERCULOSIS SANATORIUM.

IT is extraordinary what a lot of practical good at a very small cost can be done in various ways, and notably in public health matters, by merely utilising agencies already at hand, if only someone happens to think of it. An instance in point is a scheme advanced by Mr. W. Frost, mayor of Macclesfield, for treating at a time six or eight cases of pulmonary tuberculosis for a period of six weeks each, in the at present unused small-pox hospital of the borough. If the patients are selected from the crowded dwellings of the poor, where infection is being spread broadcast, they can be converted into sanitary missionaries, and thus help to diminish the disease. During their six weeks in hospital they would be educated in correct methods of living, the value of fresh air, and the methods of preventing the spread of infection to others—knowledge which they would take back home and instil into their neighbours. At the same time their own health in many cases would be materially improved. Two nurses and one maid would be a sufficient staff to do all that is required. The estimate of expenses for salaries, light, fuel, and food for the 11 persons, inclusive of the staff (the cost of food being fixed at approximately one-third additional on the ascertained cost per head at the fever hospitals), comes to £336 4*s*. To this must be added a charge during the first year of £30 for structural alterations, bedsteads, &c., making a total of £366 4*s*., which sum would be covered by a rate of 1*d*. in the £1. Rent, of course, would not have to be paid, and the nature of the work is such that in case of an outbreak of small-pox the tuberculous patients could at once be sent home and the hospital again devoted to its original purpose.

It is satisfactory to learn that this very sensible and simple plan has received the unanimous sanction of the health committee.

---

IN a telegram to the Secretary of State for the Colonies, received on Feb. 3rd, the Governor of Mauritius reports that 8 cases of plague had occurred during the week ending Feb. 2nd, with 5 deaths.

---

# ANNUAL REPORT FOR 1909 OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

## II.[1]

IN our notice of this report in THE LANCET of Feb. 4th we alluded to Sir Shirley Murphy's use in recent reports of a special life-table for London, for the purpose of indicating the mean future life-time or expectation of life, as the best-known test of the vitality of the population. An amended table appears in the present report showing the probability of living for one month from the commencement of each month in the first year of life, and the number of survivors at the beginning of each of the first 12 months after birth out of 100,000 infants born in the year 1909. To this table further columns are added showing the figures for the previous five years recalculated from the more fully corrected figures that have become available since the life-table was first introduced into the London reports.

From this table we learn that while there appears to be generally a progressive increase in the probability of living for one month, the increase is not continued into the later months of the first year of life. The corrected figures for the last five years are given in this table, and a "composite probability curve" for these years has been prepared, which indicates that, with a generally rising probability curve, there is a slightly diminished probability of living through the ninth month of life; this circumstance will be further considered presently.

### *Infantile Mortality.*

The registration of births was not compulsory in England until 1875; but since that year the national register of births has become annually more accurate, and in the last completed decennium it may be regarded as for practical purposes complete. When, therefore, it is realised that even so recently as 1891–1900 London infantile mortality had averaged 159 per 1000 births, whilst it did not exceed 108 per 1000 in the year now under review, we are struck with the significance of the life-saving that has been accomplished within a relatively short period.

From a table for London prepared in conformity with instructions drawn up by Sir W. H. Power for the Local Government Board, it appears that among the 12,686 infant deaths in London in the year under review 4158 died within a month of birth, more than half of which succumbed before the end of their first week of life. In a supplementary table, in which the mortality at each age-period is calculated upon the number of infants surviving to the age specified, London mortality within the first weeks and months of the first year after birth is shown for each year of the last five; comparison may therefore be made of the death-rates at the several stages of each year, and thus the exact periods of infant life may be ascertained at which the decrease has been most marked. The table shows that the sixth and seventh months are those in which the decrease has been relatively greatest; whilst the first and twelfth months are those in which it has been relatively least. In order to show the effect of social condition, as indicated by the extent of overcrowding, on infant mortality at different stages of the first year of life, a table has been prepared by which may be contrasted the rates of infant mortality prevailing in groups of districts arranged on the basis of relative overcrowding—this term being understood as applying to that portion of the population which lives more than two in a room in tenements of less than five rooms. The table shows that the difference in mortality is very striking when the most favoured districts, overcrowded to the extent of 7·5 per cent. only, are compared with the least favoured districts in which the proportion of overcrowding exceeds 28 per cent. Still more striking is the contrast when the mortality is stated for separate trimesters of the first year. By this means it appears that whilst among infants under the age of three months the death-rate in the worst areas is less than one-third higher than in the best, among infants at ages from 9 to 12 months the loss of life in the former areas is more than double that in the latter. If the grouping of districts is based, not on relative overcrowding, but on the percentage of children aged 5–14 years scheduled for education purposes, we find that the results are similar.

In recent years improvement in the infantile death-rate has been shared very unequally in various parts of the metropolis. For we learn that within the quinquennial period 1905–09 the fall in infantile mortality has amounted to 25 per cent. in the districts most highly favoured in other respects, whilst it has not exceeded 13 per cent. in the least favoured districts. Reference has already been made to Sir Shirley Murphy's remarks concerning the diminished probability of living noticeable during the ninth month of infant life in association with a generally rising probability curve. But the persistency since 1905 of this feature of the probability curve has suggested the further examination of the monthly mortality figures so as to ascertain the mortality per 1000 living at the commencement of each month from certain groups of diseases in each of the last five years. For this purpose a table has been prepared in which the causes of infantile mortality are grouped into three classes—(1) those causes that increase in prevalence with progressive ages, such as the common infectious diseases of childhood; (2) those causes that show relatively little variations in age incidence, such as the diseases of the tuberculous class; and (3) those causes that exhibit diminished incidence as age advances, such as premature birth, want of breast-milk, &c. With respect to the first of these groups, we note that from the first to the twelfth month there is an almost uninterrupted increase in the rate of incidence of the common infectious diseases; while as regards premature birth, want of breast milk, and "other causes," the reverse is generally true. As far as can be learnt from their mortality, tuberculous diseases show remarkable constancy of incidence from the fourth month of life onwards, whilst the age incidence curve of diarrhœal diseases rises to a maximum in the fourth month, and thereafter progressively declines. Diseases of the respiratory system—pneumonia, laryngitis, and bronchitis—show a much less regular curve, and further analysis of the figures is requisite in order to ascertain the causes determining the shape of the curve—a shape which is suggestive of increasing susceptibility, with advancing age, to some forms of respiratory disease, and of increasing resistance to others The remarkable increase in the incidence of respiratory mortality in the ninth month of life is alone sufficient to account for the depression already alluded to in the probability curve of the London life-table.

In England and Wales, also, the figures relating to respiratory diseases show a maximum incidence at the ninth month, but the excess over the eighth month is relatively less than in London. From this circumstance Sir Shirley Murphy believes that an average over a greater number of years in London will tend somewhat to reduce the disparity between the deaths from respiratory diseases in the eighth and the ninth month of life. "It is, however, clear," he proceeds, "from an examination of the death-rates from all causes in England and Wales over a series of years, that the influences operating in the first year of life are such as to produce normally a flattening, hardly amounting to a depression, of the probability curve about the eighth month, this being the natural result of the rapid decrease down to this point of the deaths from pre-natal and natal influences, on the one hand, and the increase from the sixth month onwards in the deaths from infectious diseases, and to some extent respiratory diseases on the other hand."

For the better protection of infant life in London many of the borough medical officers of health periodically circulate valuable information and instruction, which it is hoped will be fully utilised in those districts. The experience of 1909 emphasises the great advantage enjoyed by infants fed

[1] Previous notices of this report will be found in THE LANCET of Jan. 14th (p. 110) and Feb. 4th (p. 322).

at the breast, as compared with those artificially fed either wholly or in part. Prominent among topics of this kind discussed by some health officers, may be mentioned the evil effects inflicted upon nursing mothers by employment elsewhere than at home. London experience is at yet too limited to warrant the drawing of decided inferences on this important matter, but inquiry into a large number of cases in Westminster and in St. Pancras already undertaken by Dr. F. J. Allan and Dr. J. F. J. Sykes respectively points very distinctly to the advantage in regard to health enjoyed by the offspring of mothers whose occupation does not involve lengthened absence from home.

*Prevalence of Epidemic Disease.*

Among the common infectious diseases measles alone showed exceptional fatality in the year under notice, the mortality from the other infectious diseases being below the average. Only 15 cases of small-pox are known to have occurred in London, and of these two terminated fatally. But in view of the fact that the proportion of infants either exempted on account of conscientious objection or not fully accounted for as regards vaccination is gradually increasing, especially in the worst districts, it would be folly for Londoners to count upon similar immunity from small-pox in the future.

As measles is mainly a disease of early life, its mortality is very properly stated as a proportion of children living at ages under 5 years. In the year 1909 measles has been more fatal at these ages than in any other year since 1904. The sacrifice of infant and child life varied enormously in the different sanitary areas. For whilst the death-rate did not exceed 0·35 per 1000 in Lewisham, 1·60 in Stoke Newington, and 1·62 in Hampstead, it ranged upwards to 7·29 per 1000 in Finsbury, 8·54 in Shoreditch, and 11·43 in Bermondsey. The mortality from measles is largely determined by the social condition of the people, for the disease secures by far the largest number of victims in the most overcrowded districts. Information concerning the occurrence of cases of measles is derived mainly from the teachers in elementary schools. Of these occurrences account is given in the reports of the district medical officers of health, where also particulars are given of steps taken by the local authorities for the limitation of measles prevalence, either by the closure of schools, by the exclusion from school of children from invaded houses, or by the more recent method of excluding children who are not known to be protected by a previous attack. In the case of measles unusual difficulty of securing isolation is encountered because of the circumstance that in some districts many of the patients do not receive medical supervision. In Bethnal Green, for example, out of about 600 known cases at least 20 per cent. escaped medical treatment entirely.

According to the notification returns the Administrative County of London was freer from scarlet fever in the year under notice than in any other year since 1904. The reported cases did not exceed the proportion of 1·81 per 1000 in Holborn and 2·09 in the City of London, whilst they were equal to 5·78 per 1000 in Lewisham and to 7·72 per 1000 in Woolwich. The mortality, however, was relatively lowest in Hampstead, Hackney, and Battersea, and was highest in Bethnal Green. In the month of June, 1909, a serious outbreak of scarlet fever occurred in several districts of London and also in the county of Surrey. From a joint report presented by Dr. W. H. Hamer and Dr. J. H. Jones it appears to have been clearly demonstrated that the milk from a dairy farm in Wiltshire was the cause of this outbreak, although there was complete absence of evidence that the milk was infected by human agency. On the one hand, we read that scarlet fever was certainly present in the family of a man employed in the dairy, but, on the other hand, it is stated that cases of definite scarlet fever and of sore-throat had occurred in distant areas among consumers of the milk at a date antecedent to its occurrence in that family. "It is impossible," writes Sir Shirley Murphy, "to reconcile with the facts of the occurrences the view that the milk owed its infection to this family. There appeared to be interruptions to the continued infectivity of the milk, as judged by the dates of attack of the different consumers, and again, the milk appeared on one day to have been especially operative in causing scarlet fever. These variations find explanations when the details of treatment and distribution of the milk come to be studied. Varying amounts of the infected milk were pasteurised on different days, and on the day when the most mischief was done the whole of the infected milk was sent out unpasteurised." It appears that in this, as in several other outbreaks, a vesicular disease was found in the teats and udders of some of the cows, and that when the milk of one of these cows which had recently calved was brought into use after the death of the calf the infective property of the milk was first manifested.

*(To be concluded.)*

## LONDON COUNTY COUNCIL AND MEDICAL TREATMENT AND INSPECTION OF SCHOOL CHILDREN.

*The Board of Education and Medical Treatment.*

THE Education Committee of the London County Council on Feb. 1st received a report from the Children's Care Subcommittee that the Board of Education had replied to the request for the extension for 12 months of the agreements with six hospitals for the medical treatment of school children,[1] that it would consent to the continuance of the existing arrangements with the hospitals for six months only, expiring June 30th, 1911. The Board added that it did not consider that during this period the number of children treated at the hospitals should be increased, as proposed by the Council. The letter was a long one, containing the observations of the Board upon the London scheme and dealing with important questions of organisation and administration. Copies have been sent to members of the Council only with strict injunctions not to communicate the report to the press. The subcommittee stated that it was holding special meetings to consider the letter point by point, and would report at the earliest possible date. Meanwhile, the issues involved were so important that six months would not permit of adequate consideration. The Board of Education should be urged once more to extend existing arrangements (both in regard to the agreements with the six hospitals and to other agreements expiring this year) until Dec. 31st, in order that the whole scheme might come up for consideration at one time. With regard to the London Hospital the subcommittee said that serious inconvenience would be caused if the number of children to be treated was limited to that arranged for in 1910. There was considerable congestion in the aural department of the hospital, and the Council should urge the Board to accede to the application for an increase in the numbers to be treated from 4750 to 9250 cases a year, as might be found necessary. It was mentioned that the governing body of the Hospital for Diseases of the Throat, Golden-square, W., had intimated that it was unwilling to renew the agreement with the Council, but was prepared to treat under the ordinary rules children sent by the Council.

When the report came before the Education Committee Mr. BRUCE expressed the opinion that it would be foolish after the Board's letter to repeat the request for an extension for 12 months.

The Rev. J. SCOTT LIDGETT and Mr. COTTON, however, pointed out that by the time the subcommittee, Education Committee, and Council had considered the subject the summer recess would be at hand. Mr. Cotton, though an opponent of the present scheme, declared that the Children's Care Subcommittee was thoroughly in earnest. It was evident from the letter of the Board that the system required a complete overhaul, and this could not be done in six months.

The recommendation of the subcommittee to ask the Board of Education to reconsider its decision was approved.

*Statistics of Medical Inspection.*

The Children's Care Subcommittee reported that the number of children to be medically inspected to comply with the requirements of the Code for the year ending July 31st, 1911, was 149,600. The number actually seen from August 1st to Dec. 31st, 1910, was 82,847. To comply with the Board's requirements, 3400 cases, comprising only "entrants" and "leavers," should have been dealt with each week from August 1st, 1910, or 61,200 from August 1st to Dec. 31st. During this period 46,214 "entrants" and "leavers" were inspected. On Dec. 31st there was therefore

[1] THE LANCET, Jan. 21st, 1911, p. 184.

a deficit of 14,986, but prior to Oct. 20th, 1910, only part of the staff of 72 school medical officers was engaged on the examination of children coming within the approved age groups. Between that date and Dec. 31st the full staff of school medical officers dealt with 3800 cases a week. At the same rate the staff, increased to 100 as from Jan. 1st, 1911, would deal with 5280 cases a week. Thus the deficit up to Dec. 31st would be cleared off before Easter, and, in addition, children between the ages of 8 and 9, and urgent cases, would be examined.

## THE CHOLERA EPIDEMIC.

(BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

*Cholera in Russia.*

THE cholera epidemic in Russia is now almost, but not quite, extinct. The following figures are in continuation of those published in my last letter on this subject (which appeared in THE LANCET of Dec. 17th, 1910, p. 1789):—

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Week ending | Oct. | 16th | ... | 522 | cases, | 306 | deaths. |
| ,, | ,, | 23rd | ... | 175 | ,, | 119 | ,, |
| ,, | ,, | 30th | ... | 107 | ,, | 51 | ,, |
| ,, | Nov. | 6th | ... | 172 | ,, | 78 | ,, |
| ,, | ,, | 13th | ... | 86 | ,, | 40 | ,, |

These are all "corrected" figures; the following are "uncorrected":—

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Week ending | Nov. | 20th | ... | 26 | cases, | 12 | deaths. |
| ,, | ,, | 27th | ... | 33 | ,, | 17 | ,, |
| ,, | Dec. | 4th | ... | 13 | ,, | 9 | ,, |

(The above dates are all according to the Old Style.)

The totals for the whole of Russia since the beginning of the 1910 epidemic down to Nov. 20th (Dec. 3rd) are put at 215,903 cases and 100,859 deaths. In the last week in the above list (i.e., that ending Dec. 4th) the disease was confined to the towns of St. Petersburg and Baku and the governments of Kief, Perm, and Ekaterinoslav.

*Cholera in Austro-Hungary.*

Information as to the behaviour of the disease in Austria and Hungary has been far from complete. It was recently stated by the Austrian Minister of the Interior that the last case of cholera in Austria occurred on Nov. 7th, and that since the first case on August 23rd there had been in all 15 cases and 5 deaths. In Hungary the following cases and deaths have been recorded:—

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| Between | Oct. | 30th | and | Nov. | 5th | ... | 23 | cases, 13 | deaths. |
| ,, | Nov. | 6th | ,, | ,, | 12th | ... | 19 | ,, 6 | ,, |
| ,, | ,, | 13th | ,, | ,, | 19th | ... | 14 | ,, 7 | ,, |
| ,, | ,, | 20th | ,, | ,, | 26th | ... | 8 | ,, 2 | ,, |
| ,, | ,, | 27th | ,, | Dec. | 3rd | ... | 2 | ,, 2 | ,, |

The cases and deaths have been confined to the counties of Bacs-Bödrog, Heves, Torontal, and Baranya; and the highest figures have been returned from the two first-named. In addition to the above, single cases occurred early in November in each of two communes in the district of Irig, in Croatia. On Dec. 19th the Turkish Consul in Budapest telegraphed that the last case of cholera had occurred there on Nov. 2nd, and that on the day of telegraphing he had learnt that 8 cases had occurred in the provinces—5 at Nemetecska and 3 at Nagybecskerek; precautionary measures, he added, were still maintained throughout Hungary.

*Cholera in Italy.*

Reports from Italy are also incomplete. The following figures have been communicated by the Turkish Embassy in Rome:—

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Week ending | Nov. | 9th | ... | 88 | cases, | 21 | deaths. |
| ,, | ,, | 16th | ... | 72 | ,, | 25 | ,, |
| ,, | ,, | 23rd | ... | 44 | ,, | 10 | ,, |
| ,, | ,, | 30th | ... | 19 | ,, | 2 | ,, |
| ,, | Dec. | 7th | ... | 39 | ,, | 12 | ,, |

In the first of these weeks the disease was prevalent in the provinces of Caltanisetta, Campobasso, Caserta, Girgenti, Lecce, Naples, Palermo, Rome, Terracina, Salerno, and Trapani; in the last the list of infected provinces was reduced to four—those of Aquila, Caserta, Girgenti, and Palermo. The provinces of Caserta, Naples, Lecce, and Palermo have furnished the highest figures, but there have been a considerable number of cases in that of Rome. In the last week in the list the province of Palermo returned 33 out of the 39 cases, and of these 25 (with 10 deaths) had occurred in a lunatic asylum (which had also furnished several cases in the preceding weeks).

*Cholera in Bulgaria.*

Between Oct. 31st (Nov. 13th) and Nov. 7th (20th) 4 cases of cholera with 3 deaths occurred at Varna. These cases apparently all developed among the "contacts" who were put under "cordon," in connexion with the imported case from Constantinople mentioned in my last letter. Among 27 other persons isolated in one of the Varna hospitals 2 other cases occurred.

*Cholera in Constantinople and Turkey in Europe.*

The outbreak of cholera in Constantinople has now almost disappeared. The following are the weekly returns (in continuation of the figures formerly published):—

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Week ending | Nov. | 28th | ... | 168 | cases, | 109 | deaths. |
| ,, | ,, | Dec. 5th | ... | 117 | ,, | 75 | ,, |
| ,, | ,, | ,, 12th | ... | 98 | ,, | 48 | ,, |
| ,, | ,, | ,, 19th | ... | 215 | ,, | 125 | ,, |
| ,, | ,, | ,, 26th | ... | 156 | ,, | 98 | ,, |
| ,, | ,, | Jan. 2nd | ... | 62 | ,, | 46 | ,, |

The daily returns have shown great fluctuations—partly due, no doubt, to the incompleteness of the machinery for obtaining exact information. The daily curve, however, shows some points of interest; it indicates, firstly, a period of sporadic cases only (lasting from Sept. 13th to Nov. 3rd), followed by a marked, though fluctuating, rise to a maximum of 38 cases in one day, on Nov. 22nd. The figures then fell more or less steadily, till on Dec. 11th only 9 cases were recorded. But the curve then rose rapidly again, and on Dec. 18th, and again on the 21st, as many as 43 cases were seen in a single day. The fact that this marked rise occurred just at the time of the Moslem fêtes of Kûrban Bairam must be regarded as something more than a mere coincidence. The number of cases has since steadily fallen, and on Jan. 4th only one case was registered. Among the troops of the capital the epidemic has apparently disappeared. The late prevalence of cholera in this city has coincided with a remarkable spell of warm, spring-like weather, more like May than December; but it must be added that this spell still continues and that the cholera curve has fallen in spite of it.

The figures for the troops outside Constantinople will perhaps never be accurately known. In the Touzla lazaret (on the Gulf of Ismidt) at least 250 cases, with 187 deaths, occurred, and the vast majority of these were among the troops interned there. From a large number of places (Rodosto, Dedeagatch, Hademkeui, Samsoun, and Salonica) in the European and Asiatic provinces news has been received of more or less severe outbreaks of the disease among the troops returning to their quarters after the autumn manœuvres. It is impossible to calculate even approximately how many men were attacked in these circumstances, but the totals must be considerable.

At Salonica there has been a mild outbreak of cholera in the civil population and among the troops. In the former 7 cases and 4 deaths occurred down to Dec. 17th; 2 cases and 2 deaths in the following week; and 2 cases and 2 deaths in the week ending Dec. 31st. In the troops (mostly conscripts in this instance) 29 cases and 9 deaths were recorded down to Dec. 17th, and 1 fatal case subsequently. Cholera also appeared at Cedes and Seres, in the Salonica vilayet, and the totals for that province down to Dec. 31st are put at 52 cases, with 27 deaths.

*Cholera in Asiatic Turkey.*

In the vilayets of Erzerum and Van the cholera outbreak seems to have become extinct in the early days of November. In that of Trebizond the following figures have been recorded (in continuation of those in my last letter):—

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Week ending | Nov. | 27th | ..... | 47 | cases, | 15 | deaths. |
| ,, | ,, | Dec. 4th | ..... | 42 | ,, | 16 | ,, |
| ,, | ,, | ,, 11th | ..... | 13 | ,, | 8 | ,, |
| ,, | ,, | ,, 18th | ..... | 5 | ,, | 3 | ,, |

The total number of cases in this vilayet has been 746 and that of deaths 394.

At Samsoun, on the south shores of the Black Sea, 18 cases with 18 deaths were recorded between Nov. 13th and Dec. 5th. Cases of the disease have also been reported from Broussa, Konia, Moussoul, Jezireh, and other places in the vilayets of Asia Minor, including those of Diarbekir, Mamouret-ul-Aziz, and others.

In the vilayet of Bagdad the following are the latest weekly returns:—

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Between | Nov. 20th | and | Nov. 25th | ... | 55 | cases, | 69 | deaths. |
| ,, | ,, 26th | ,, | Dec. 4th | ... | 42 | ,, | 30 | ,, |
| ,, | Dec. 5th | ,, | ,, 11th | ... | 22 | ,, | 16 | ,, |
| ,, | ,, 12th | ,, | ,, 17th | ... | 18 | ,, | 24 | ,, |
| ,, | ,, 18th | ,, | ,, 25th | ... | 29 | ,, | 33 | ,, |
| ,, | ,, 25th | ,, | ,, 26th | ... | 3 | ,, | 2 | ,, |

These figures are undoubtedly imperfect. The totals for the Bagdad vilayet since the beginning of the outbreak down to Dec. 26th are put at 814 cases and 718 deaths.

At Basra, near the head of the Persian Gulf, 10 further cases with 9 deaths were seen between Nov. 18th and 26th; and 1 case with 1 death between Nov. 26th and Dec. 3rd. No other cases have been reported since.

In Smyrna the returns have been as follows:—

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| From | Nov. 13th | to | Nov. 24th | ... | 22 | cases, | 16 | deaths. |
| ,, | ,, 25th | ,, | Dec. 4th | ... | 17 | ,, | 14 | ,, |
| ,, | Dec. 5th | ,, | ,, 11th | ... | 27 | ,, | 17 | ,, |
| ,, | ,, 12th | ,, | ,, 18th | ... | 9 | ,, | 9 | ,, |
| ,, | ,, 19th | ,, | ,, 25th | ... | 5 | ,, | 5 | ,, |
| ,, | ,, 26th | ,, | Jan. 1st | ... | 12 | ,, | 8 | ,, |

The totals here are put at 92 cases, with 69 deaths.

*The Pilgrimage and the Cholera: an Infected Haj.*

The fêtes of Kûrban Bairam fell this year between Dec. 11th and 14th. It seemed impossible that the Haj should escape being an infected one, with cholera more or less severely epidemic in Russia, in the European and Asiatic provinces of Turkey, in Muscat, in Persia, and elsewhere. Yet for a time it appeared as though the impossible had happened. The fêtes at Mecca, Mina, and Arafat passed without any appearance of the disease; nearly a fortnight went by, and the telegrams still reported the health of the pilgrims favourable. On previous occasions when cholera has broken out in the Haj it has almost invariably been before or at the time of the greatest agglomeration of pilgrims in connexion with the Bairam fêtes; so, as time went on and no signs of cholera appeared, the hope was for a time justified that this year's Haj would, in spite of all fears to the contrary, remain a cholera-free one. But this hope has now been disappointed. On Dec. 26th a telegram from Mecca reported the occurrence of two "*cas cholériformes*" without further details save that the results of a bacteriological examination were uncertain. About the same time an undoubted cholera case was landed at the Tor lazaret from a pilgrim steamer returning from Jeddah. For several days telegraphic communication with Mecca was interrupted; since it has been re-established the existence of cholera there has been placed beyond a doubt. At least 12 cases have occurred. A considerable number of other cases of the disease have also been landed from pilgrim steamers at the Tor lazaret. The Haj has consequently been declared a cholera-infected one, and measures taken in consequence. These include a five days' quarantine in the lazaret of Tebuk for pilgrims returning by the Hedjaz Railway. The fact that the disease only broke out among the pilgrims after they had begun to disperse, when the Bairam fêtes were over, must be regarded as a most fortunate one. The next news of the outbreak may be expected from Medina, where a majority of the pilgrims flock to after leaving Mecca.

*Cholera in Muscat.*

In the week ending Nov. 26th 4 deaths from cholera were registered in Muscat; in that ending Dec. 3rd there were 3 more; and on Dec. 10th the port was officially declared cholera free.

*Cholera in Persia.*

Reports from Persia throw a very imperfect light on the course of the cholera epidemic in that country. The following is a brief summary of the information hitherto received. At Enzeli, on the Caspian Sea, cholera appeared on August 20th; down to Dec. 9th there had been 122 cases there, with 81 deaths. At Resht, from Oct. 13th to Dec. 11th, 118 deaths were recorded. The disease prevailed more or less extensively in the province of Azerbaijan, in the neighbourhood of Tabriz. In the Khorassan province it caused a serious epidemic at Meshed, where between Sept. 11th and Nov. 6th 262 cases and 109 deaths were registered. It appeared in Daré-Djaz, Mohammedabad, and Golkandar, to the north and north-west of Meshed. At Turbat-i-Haidari (near the Afghan frontier) 66 cases with 25 deaths occurred between Oct. 10th and Nov. 15th. In the south-west of Persia there were at Hamadan 96 cases and 48 deaths between Oct. 2nd and Dec. 12th, and at Kermanshah 531 deaths between Oct. 5th and Nov. 10th (and apparently none since). At Kirman 77 cases and 25 deaths were recorded down to Nov. 30th. At Mohammerah, on the Shatt-ul-Arab river, below Basra, there were 58 cases and 22 deaths between the beginning of November and the 26th of that month (and apparently none since). The disease has also prevailed at Mollah Ali, Birdjend, Assadabad, Fathabad, Nir, Ahar, Kalat-i-Nadiri, Lutfabad, and elsewhere.

*Cholera in Tripoli (Africa).*

In Tripoli (Barbary) only 3 cases with 2 deaths were recorded between Nov. 22nd and Dec. 1st, and only 1 death between Dec. 1st and 8th. On the 13th it was reported that no fresh case had been seen since the 4th. The totals here are put at 290 cases with 235 deaths. But consular reports place the totals at 328 cases with 226 deaths. Of these deaths, no less than 219 are said to have occurred among Jews, 4 among Moslems, and 3 among Christians.

*Cholera in Tunisia: A Correction.*

In recent letters to THE LANCET on this subject I have mentioned the occurrence of many cases of, and deaths from, cholera in the island of Jerba, off the coast of Tunisia. It appears, however, that this was erroneous, and that the telegrams received from that island and furnishing the figures that I had quoted related to the epidemic in Tripoli (Barbary) and not to any outbreak in the island itself. I must add that there was nothing in those telegrams to indicate that this was the case, so that it was but natural to assume that the figures related to the island. So far as is known here cholera has not appeared in any part of Tunisia in the past year.

Constantinople, Jan. 5th.

## BRITISH MEDICAL BENEVOLENT FUND.

AT the January meeting of the committee 27 cases were considered and grants amounting to £209 made to 20 of the applicants. Appended is an abstract of the cases relieved.

Daughter, aged 59 years, of late M.R.C.S. No income; unable to earn a living on account of persistent ill-health. Recommended by Mr. C. E. A. MacLeod, F.R.C.S. Voted £12.

Widow, aged 47 years, of L.S.A. Husband's means exhausted by a long illness ending in death a few months ago, and the small sum obtained for the death vacancy was practically all swallowed up by debts. Has taken a house and hopes to support herself by receiving boarders. Four children, all dependent. Recommended by Dr. Walter Broadbent. Voted £10.

Daughters, aged 62 and 60 years, of late M.R.C.S., L.S.A. Formerly teachers and now endeavouring to maintain themselves by a small boarding-house, but have had a bad year. Recommended by Dr. J. Macfee. Voted £10.

M.B., C.M. Edin., aged 61 years. Incapacitated by hemiplegia; no income. Recommended by Dr. William Bruce. Voted £2 and to be further considered next month.

M.R.C.S., aged 63 years. Was obliged to retire three years ago owing to paralysis, and has supplemented a small annuity by the proceeds of the sale of practice, now exhausted. Recommended by Dr. J. Mitchell Bruce, Vice-President. Voted £10.

Widow, aged 50 years, of L.R.C.P. Edin. Since husband's death has supported herself by taking boarders, but has been compelled to contract some debts. Two sons unable to assist, and one daughter, delicate, who does the house-work. Recommended by Dr. J. Bligh. Voted £12.

Daughter, aged 73 years, of late M.R.C.S. Supplements an income of £20 a year by needlework, but is becoming incapacitated by rheumatoid arthritis. Relieved 12 times, £113. Recommended by Mr. F. W. Way. Voted £12.

Widow, aged 40 years, of M.D. R.U.I. Income £25 a year. One child 2 years old, which makes it extremely difficult for applicant to earn anything. Relieved once, £10. Recommended by Mr. J. R. Lownds Voted £10.

Widow, aged 61 years, of M.R.C.S. No income; children only able to give very slight help. Relieved seven times, £72. Recommended by Mr. E. C. Barnes. Voted £12.

Widow, aged 57 years, of L.R.C.P. Irel. No income; unable to earn anything on account of a deformity. Children cannot help. Relieved seven times, £56. Recommended by Dr. C. W. Buckley. Voted £12

M.R.C.S., aged 83 years. Only income a small Poor-law superannuation allowance. Children unable to help and one still dependent. Relieved once, £12. Recommended by Dr. Henry Davy. Voted £12.

M.D.Edin., aged 69 years. Obliged to retire some years ago on account of ill-health, and has since lost all his means through a series of family misfortunes. Relieved once, £10. Recommended by Sir George Beatson, K.C.B., honorary local secretary. Voted £10.

Daughter, aged 53 years, of late M.R.C.S. No income; eyesight defective and can only earn a few shillings a week. Relieved once, £18. Recommended by Mr. W. M. Beaumont. Voted £18, to be shared with two afflicted sisters.

Widow, aged 56 years, of L.S.A. Only income a small pension; children cannot help. Relieved once, £12. Recommended by Mr. R. H. Luce, honorary local secretary. Voted £5.

Daughter, aged 54 years, of late M.R.C.S. Keeps a boarding-house, but is in temporary difficulties owing to a couple of bad seasons. Relieved once, £10. Recommended by Mr. J. Jarvis. Voted £10.

Daughter, aged 59 years, of late M.R.C.S. For many years was a matron at a boys' school, but is now dependent on small earnings from music lessons and sewing. Relieved four times, £48. Recommended by Dr. C. J. Gibb. Voted £12.

Widow, aged 53 years, of M.R.C.S. No income, and is dependent on this Fund and help given by relatives. Children barely self-supporting. Relieved 15 times, £174. Recommended by Dr. Charles Steele. Voted £5.

Daughter, aged 34 years, of late M.R.C.S. Trained as a nurse, but found herself unable to act as such owing to continued bad health, which necessitated three or four surgical operations. Now endeavours to support herself by making marmalade. Relieved six times, £53. Recommended by Dr. E. Hyla Greves. Voted £10.

L.R.C.P.Edin., aged 52 years. Used to have a good practice in London, but owing to continued ill-health is now penniless and hopes shortly to get a ship's surgeoncy. Relieved once, £5. Recommended by Mr. J. Roche Lynch and Mr. H. W. Kiallmark. Voted £5.

Daughter of late M.D., who practised in Devonshire. Was comfortably provided for, but lost practically everything through the negligence of a trustee, and now endeavours to support herself by taking boarders. Relieved twice, £25. Voted £10.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole street, London, W.

# THE SERVICES.

## ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: R. S. Bernard to the *Indefatigable*, on recommissioning; and S. H. Birt to the *Carnarvon*, on recommissioning. Staff-Surgeon: M. L. M. Vaudin to the *Apollo*. Surgeons: D. H. C. Given to the *Tamar*, additional, for the *Rosario*, and to the *Rosario* on recommissioning; E. MacEwan to the *Warrior*; and W. R. Harrison to the *Indefatigable*, on recommissioning.

## ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenant-Colonels are placed on retired pay:—James M. Reid (dated Jan. 29th, 1911), Charles W. S. Magrath (dated Feb. 2nd, 1911), and Louis W. Swabey (dated Feb. 3rd, 1911).

Lieutenant-Colonel John B. W. Buchanan retires on retired pay (dated Feb. 4th, 1911).

Major James W. Jennings, D.S.O., is placed on retired pay (dated Jan. 31st, 1911).

Lieutenant-Colonel R. R. H. Moore, from Bulford Camp, Salisbury Plain, has taken over duties as Administrative Medical Officer of the Belfast District. Lieutenant-Colonel J. R. Forrest has been transferred from Cork to Tipperary. Lieutenant-Colonel M. O'Halloran, from Shorncliffe, has joined for duty at Canterbury. Lieutenant-Colonel F. W. Caton Jones, from Tidworth Park, has taken over command of the station hospital at Quetta. Major D. Harvey, honorary surgeon to H.E. the Viceroy of India, has been appointed to the medical charge of the transport s.s. *Rewa*, leaving Karachi for Southampton on March 31st, vice Captain C. G. Thomson, who will proceed on duty. Major W. C. Poole has been granted three months' general leave in India. Major H. W. Grattan, sanitary officer of the Eighth (Lucknow) Division, has been transferred from Naini Tal to Lucknow. Major J. V. Forrest has arrived at Cairo on termination of his leave. Major L. F. Smith, medical officer in charge of the brigade laboratory at Nowshera, has been appointed to officiate as Sanitary Officer of the First (Peshawar) Division, during the absence on special duty of Major R. J. Blackham. Major C. J. O'Gorman, D.S.O., has been appointed to the officiating command of the station hospital at Peshawar. Major F. J. C. Heffernan, from Fyzabad, has taken up duty in the London District. Major M. Swabey has been transferred from Jubbulpore to Secunderabad. Major A. F. Tyrrell, from Fermoy, has been appointed for duty at Tipperary. Major G. St. C. Thom, medical officer in charge of the station and cantonment hospital at Subathu, Simla Hills, has been granted five months' leave of absence home from India. Major H. A. Hinge, Staff Officer for Mobilisation Stores, Ninth (Secunderabad) Division, has arrived home from India in the transport s.s. *Plassy*. Major A. H. Morris, specialist sanitary officer, Scottish Command, has been detailed to embark for Malta in the transport s.s. *Soudan* on Feb. 25th. Captain G. J. Houghton, at present serving at Queenstown, has been placed under orders for a tour of service on the West Coast of Africa (Sierra Leone). Captain A. T. Frost has taken up duty as Specialist in Dermatology and Venereal Diseases in the Dublin District. Captain C. H. Furnival, on arrival in India, has been appointed to the Southern Army and posted to the station hospital at Secunderabad. Captain P. A. Lloyd Jones, from Malta, has joined for duty in the Cork District. Captain W. McConaghy has been transferred from Oxford to Tidworth Park. Captain R. C. Hallowes, on arrival home from Cairo, has been posted to the Belfast District. Captain A. C. Adderley, from Lichfield, has embarked for a tour of duty in South Africa. Captain A. C. Duffey, at present serving in the Dublin District, has been placed under orders to embark for India on March 3rd next for duty with the Northern Army. Captain E. W. Powell has taken over charge of the Brigade Research Laboratory at Aden. Captain L. V. Thurston, from Khanspur, has been appointed to the Irish Command for duty in the Cork District. Lieutenant C. H. Stringer and Lieutenant L. F. K. Way have joined for duty in the Southern Command. Lieutenant F. H. Somers-Gardner, from Hilsea, has been posted to Pontypridd. Lieutenant J. James, from Woolwich, has embarked for South Africa.

## INDIAN MEDICAL SERVICE.

His Excellency the Governor of Bombay has appointed Lieutenant-Colonel L. F. Childe Professor of Medicine, Clinical Medicine, and Therapeutics at the Grant Medical College, Bombay. Major A. G. Sargent has been appointed to officiate as Civil Surgeon at Belgaum. Major T. S. Novis has taken up duty as Presidency Surgeon, Bombay (First District), in succession to Captain L. P. Stephen. Major H. J. R. Twigg has taken over charge of the Yeravda Central Prison, in succession to Captain J. Lowson. Major B. Deare has been selected to succeed Major R. Maddox as Civil Surgeon at Darjeeling while on furlough. Captain L. B. Scott, Bombay, has received an extension of his leave. The services of Captain W. J. Collinson, on plague duty in the Punjab, have been replaced at the disposal of the Government of India in the Home Department on his return from leave. Captain R. Kelsall has been appointed to the Civil Medical Charge of the Thayetmyo District (Burma) in succession to Captain R. D. MacGregor, posted on special duty. Captain W. L. Harnett has taken over charge as Specialist in Prevention of Disease at the Brigade Research Laboratory, Jubbulpore. Captain J. C. S. Oxley, civil surgeon at Amraoti, has been granted privilege leave, combined with furlough and study leave, home from India for one year and eight months. Major J. F. James has been appointed Civil Surgeon at Jalpaiguri. The services of Captain A. S. M. Peeble have been replaced at the disposal of the Army Department. Captain W. H. Odlum, medical officer of the 30th Lancers, has been appointed to the Civil Medical Charge of Jhansi during the absence on leave of Captain H. W. Illius. Lieutenant W. D. Keyworth has been appointed Specialist in Midwifery and Diseases of Women and Children to the Sixth (Poona) Division.

## TERRITORIAL FORCE.

### *Royal Army Medical Corps.*

*For attachment to Units other than Medical Units.*—Hugh Paterson (late Second Lieutenant, 4th Battalion (Queen's Edinburgh Rifles, The Royal Scots (Lothian Regiment)), to be Lieutenant (dated Nov. 17th, 1910).

## HONORARY PHYSICIAN TO THE KING.

Lieutenant-Colonel Robert S. F. Henderson, Royal Army Medical Corps, has been appointed an Honorary Physician to the King, and has been granted the brevet rank of Colonel, vice Surgeon-Major-General J. Sinclair, deceased.

## DEATHS IN THE SERVICES.

Lieutenant-Colonel Alfred William Frederick Street, late of the Indian Medical Service, recently at Norsey Manor, Billericay, at the age of 58. He took part in the Afghan

war from 1878–1880 and was present at the action on the Helmund, the battle at Maiwand, and the defence of Kandahar (mentioned in despatches, medal and clasp). He served in the Burmese expedition, 1886–7 (mentioned in despatches, medal and clasp, and the Distinguished Service Order).

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The *Journal of the Royal Army Medical Corps*, apart from the more strictly scientific subjects, frequently makes its pages interesting by giving short biographies of past service worthies. The February issue contains an account of the life of Robert Jackson, Inspector-General of Hospitals, who was born at Stone Byers near the Falls of Clyde in 1750. "Many army medical officers," says Major H. A. L. Howell, the author of the article, "have attained greater honours, but few men have done more to improve the condition of the British soldier and the army surgeon." Other articles are an important Report on the Determination of the Amount of Tin in Tinplate used for Canning Preserved Food, by Major W. O. Beveridge, D.S.O.; a Note upon Yellow Fever, Bilious Remittent and Remittent Fevers in West Africa, by Sir Rubert Boyce, F.R.S.; and Blood-Culture in Typhoid Fever, by Major S. L. Cummins.

MEASLES AT THE ROYAL NAVAL COLLEGE, DARTMOUTH.

The *Times* states that over 60 cases of German measles and other minor ailments among the naval cadets at the Royal Naval College, Dartmouth, are under treatment. The Prince of Wales and Prince Albert are in good health.

Surgeon-Lieutenant-Colonel C. R. Kilkelly, C.M.G., M.V.O., has tendered his resignation as house governor and medical superintendent of the Osborne House Convalescent Home for Army and Navy Officers.

# Correspondence.

"Audi alteram partem."

## GIRLS' SCHOOLS, GAMES, AND NEURASTHENIA.

*To the Editor of* THE LANCET.

SIR,—Having read with much interest and agreement Dr. Robert Jones's letter on Girls' Schools, Games, and Neurasthenia, in THE LANCET of Feb. 4th, I am impelled to write and endorse heartily most of what he says.

Having had 12 years' experience of nervous work amongst women and girls, I feel strongly also that the practically continuous time table at a large number of the best schools for girls is responsible for much of the restless incapacity to interest and occupy themselves satisfactorily which manifests itself later when these same girls return to their homes. To it, too, is due the fact that valuable and character-building knowledge is so ill assimilated that it fails to make life a comprehensible and interesting whole to the girl, who should feel it only too short in which to compass the many activities which make their appeal to the efficiently educated individual.

The failure to make life, practically anywhere in the world, interesting, is the worst accusation that can be brought against any system of education—and it can with justice be brought against much of the education of girls to-day. The reason appears to me to be that urged by Dr. Jones—i.e., that with a continuous round of lessons and games, the knowledge absorbed from both has no time in which to be digested. The girls have no time in which to see how knowledge applies to life. It is this assimilation which makes the competent, self-reliant woman, who will be able to enjoy applying what she has learnt to whatever circumstances she may find herself in—who will be able to regard games in their proper proportion, and not become hipped and morbid because there is no hockey team in her neighbourhood, wandering aimlessly through life, like one I know of, who said she had sold her bicycle because she found it took so much shorter a time to bicycle than to walk, and she did not know what to do with her days.

This demand for more free time for development of individuality and character is not met by the argument that the girls will only use the time given them badly. If this be so, what then is likely to occur when they have the management of far more of their time on leaving? Time is like money and can only be understood in the use of it. What Dr. Jones says as to the mental effect of the separation of exercise from work is exceedingly true. While having no quarrel with games, which are excellent in their place, there is a feeling of satisfaction in getting exercise from doing practical work which has no counterpart in games. I know of one school where the pupils laid out most of the grounds with excellent results. This was an attempt "to establish a proper coördination of the different branches of knowledge material."

In what Dr. Jones calls "the wild cult of athleticism" by girls, or rather by their teachers for them, as a means to health, it is sometimes forgotten that sound health is the power of ready adaptation to as widely different conditions as possible, and that it is as truly a test of health to be able to sit up for several nights in succession, and to stay for a week in the house if necessary, as it is to be able to walk 15 miles or play a hard game of hockey without showing signs of deterioration, mental, moral, or physical, under any of these stresses. One thing is sure, that the physique, well cultivated and adapted to games, does not alone protect from nervous breakdown, and if the girl be incidentally led to think of her own physical or mental development as the important matter apart from its use, it may even "carve the way for the worst type of nerves"—characterised by egoism, introspection, hypochondriasis, and consequent depression.

"This is the true joy of life, the being used for a purpose recognised by yourself as a mighty one; the being thoroughly worn out before you are thrown on the scrap heap; the being a force of nature, instead of a feverish, selfish clod of ailments and grievances, complaining that the world will not devote itself to making you happy." (George Bernard Shaw.)

I am, Sir, yours faithfully,

Hove, Feb. 6th, 1911. A. HELEN A. BOYLE.

## THE NEW BUILDING OF THE ROYAL SOCIETY OF MEDICINE.

*To the Editor of* THE LANCET.

SIR,—The praiseworthy effort to erect a building worthy of the Royal Society of Medicine, and especially for the housing of the magnificent library, deserves encouragement in every way. It must, however, be borne in mind that to Fellows resident in distant parts of the world very little benefit accrues beyond the receipt of the Proceedings. For us the departure in library practice (initiated by the Secretary, Mr. MacAlister), in being able to get abstracts made on any subject of interest to the worker, is invaluable. It does not demand a great tax on the imagination to appreciate the position of absolute deadlock for want of references.

I am convinced that if this procedure were more widely known it would induce a number of workers to join the society who up to the present have stood aloof, as the benefits corresponding to a three-guinea subscription were not apparent. It must necessarily involve some expenditure, but it appears to be an investment in the right direction and aims at carrying out the true object of the society.

I wish to extend my personal thanks to the council of the Royal Society of Medicine for the departure, and to express the hope that it will be continued and encouraged, and published more widely.

I am, Sir, yours faithfully,

Johannesburg, Jan. 16th, 1911. G. A. E. MURRAY.

## SEASONAL COLOUR CHANGES.

*To the Editor of* THE LANCET.

SIR,—I am endeavouring to collect all the facts I can bearing upon the change which takes place by the animal which is the brown stoat in summer and the white ermine in winter. Some important questions of physiology are involved in its explanation. Does the change occur as a matter of season independently of temperature, or is it connected with actual cold? At what precise period of the year does it usually begin? When an animal has been in winter plumage—more correctly peltage—at what date and under what conditions does it again become brown? We have recently obtained at the Haslemere Museum a beautiful ermine of this

winter's production. It might be thought that we have had no cold this winter, but weather chronologists assure us that the temperatures in November were exceptionally low, although December was the reverse. If any of the readers of THE LANCET can supply me with facts they will be very valuable. Many of your country residents may have good opportunities of obtaining specimens. We want illustrations of all stages, whether records of facts or, still better, the bodies of the animals. The latter should be sent to me at the Educational Museum, Haslemere, Surrey. It is not only developed specimens of either condition that are wanted, but especially those in the transition stage. I scarcely know a single specimen in our museums which illustrates the winter to summer changes, and is labelled as such.

I am, Sir, yours faithfully,
JONATHAN HUTCHINSON.

Gower-street, W.C., Feb. 6th, 1911.

## SCHLEIDEN AND SCHWANN.

*To the Editor of* THE LANCET.

SIR,—The most fundamentally important biological discovery of modern times undoubtedly is the cell theory, which is as supreme for biology as for pathology. It is therefore desirable that everyone interested in the progress of modern science should be accurately informed as to the events which led to this high attainment.

The note upon Schwann's work, which appeared in THE LANCET of Jan. 7th, does justice to him in this direction; but there is a serious omission—the antecedent work of Schleiden, which was crucial for the cell theory, is disregarded and even disavowed. It is desirable that the names of Schleiden and Schwann should be jointly remembered as the founders of the cell theory; but if we are compelled to discriminate between the two, it must be stated that it is Schleiden's work that is really indispensable, since he first established on a broad scientific basis the cellular nature of all forms of vegetable life. It is not merely the items of knowledge that he discovered, but the method he employed, that constitutes his special distinction. Hence when he founded vegetable morphology he also founded morphology in general, for Schwann's work was but an extension of his method to the animal world.

Schleiden fought bravely against the tyranny of the spirit of detail, which dominated his age as it does ours. His work was a protest against the narrow spirit of specious specialism, with its worship of sterile details, and its aversion to all else. He was far in advance of his age. Schleiden's researches (1837) established for the first time the cell as the elementary unit of all forms of vegetable life, the essential solidarity of which was thus made manifest. Before Schleiden's day many attempts had been made to institute analogies of this kind between the great divisions of the animal and vegetable world, but without success. Schleiden's work prepared the way for effecting this comparison, which was soon afterwards (1838) carried out by one of his acquaintances—Theodor Schwann.

The most fruitful years of Schwann's life were those he spent with the celebrated Johannes Müller, assisting in the formation of his anatomico-pathological museum in Berlin. It need hardly be mentioned that one who had thus come into personal contact with the wide-ranging genius of Müller—the inspirer and intellectual father of so many of Germany's greatest scientific leaders—was certain to have had his mind illuminated in no ordinary degree in all that appertained to the great biological problems of the age. In this connexion it is of interest to note that, even at this early stage, Müller had already demonstrated the cellular nature of the notochord and of cartilage. It is, therefore, not surprising to find that it was in Müller's "incredibly primitive" laboratory that the cell theory of animal structures was established by Schwann.

It will be no disparagement of Schwann's merit if I ask this question: How much was he indebted for his inspiration to Schleiden and to Müller? To the former he has acknowledged his indebtedness; and the services of the latter were probably of such a kind as not to require formal recognition. In the preface of his celebrated work, "Microscopical Researches into the Accordance in the Structure and Growth of Animals and Plants" (1839), Schwann says:—

> Schleiden communicated the results of his investigations to me prior to their publication in 1837. The resemblance of the cells of the chorda dorsalis to vegetable cells, which Johannes Müller had previously noticed, had often struck me, but nothing resulted from it. The discoveries of Schleiden, however, led me to more extended researches. I compared the cells of cartilage and of the chorda dorsalis with vegetable cells, and found the most complete accordance.

Further observations having yielded similar results, he was soon able to show that Schleiden's generalisations were in every respect applicable also to the animal world. In conclusion, it remains only to be added—and very necessary it is to make the addition in these days of forgetfulness—that the discoveries of Schleiden and Schwann were rendered possible by small but difficult mechanical improvements in the microscope, which converted it from a mere toy into the efficient scientific instrument with which everyone is now so familiar. Very noteworthy is it that these improvements took nearly two and a half centuries to effect; for the microscope, which was invented near the end of the sixteenth century, was not rendered really serviceable until after 1830.

I am, Sir, yours faithfully,
Walton-by-Clevedon, Jan. 21st, 1911. W. ROGER WILLIAMS.

## THE DEATH OF HEROD AGRIPPA.

*To the Editor of* THE LANCET.

SIR,—I think the following notes of a case in the Cawnpore General Hospital in 1857 afford a better explanation of the death of King Herod than any quoted in THE LANCET of Jan. 7th, p. 44.

In 1857 I arrived at Cawnpore in medical charge of a detachment of the 65th Foot, very soon after General Outram and General Havelock had left to relieve the Lucknow garrison; and I was then attached for duty to the General Hospital, Cawnpore. My friend Charles Julian Jackson was also attached for duty to the same hospital, and he showed me a case that had been admitted under his care of a soldier suffering from (fly-blow) maggots in his nostrils. With great care and trouble these were removed and the man protected with mosquito-curtains and when well was discharged to duty.

Not long after the same man was re-admitted suffering in the same way, but to a greater degree, as the maggots had penetrated to the throat, and eating into an artery, the man died. This man was a very heavy sleeper, and slept with his mouth wide open, which will account for the access of flies to his nose. I also had under my own care a soldier who, from want of cleanliness, had maggots under his long finger-nails, but these were easily removed.

Anyone who has seen, as I have, the rapid destruction of sheep from the maggot-fly, will not doubt the destructive power of the fly where it can get a lodgment. Where sheep are not dipped to prevent the attacks of the fly it is absolutely necessary to carefully inspect them twice daily. I believe that in some cases live maggots are deposited instead of eggs.—I am, Sir, yours faithfully,

BERNARD KENDALL,
Upper Norwood, Jan. 9th, 1911. Surgeon-Major (Retd.), I.M.S.

## TURIN INTERNATIONAL EXHIBITION, 1911: THE BRITISH SECTION.

*To the Editor of* THE LANCET.

SIR,—It has been decided that in the British Section of the approaching Turin Exhibition chemical and physical apparatus shall be shown, as far as possible, in a truly practical and novel manner; and I trust you will afford me, through the medium of your valuable columns, an opportunity of giving information to the public regarding the scheme. Generally speaking, no means are provided at exhibitions for demonstrating the utility of the instruments exhibited; and it has been felt that it would be a very great improvement to show apparatus as it would be used in a laboratory.

Accordingly for the British Chemical Section of the Turin Exhibition arrangements are now approaching completion by which, it is anticipated, there will be on view at least two well-equipped chemical laboratories, with such work going on as will effectively illustrate various interesting processes. In addition, there will be a large space available for the display in show-cases of chemical products and apparatus not in use in the laboratories. Smaller rooms will be provided for certain special appliances. The court devoted to

scientific instruments will be of similar design. Here also arrangements are being made for the display of apparatus ready for work, electric supply where needed being provided. The equipment of a large dark room is under consideration, and in this projection apparatus, such as oscillographs, spectroscopes, optical lanterns, and photometers, could be shown to advantage.

The organisation of the exhibits referred to has been placed by the Exhibitions Branch of the Board of Trade in the hands of Dr. F. Mollwo Perkin, under the direction of a joint subcommittee of the Chemical Industries Committee and the Mathematical and Scientific Instruments Subcommittee. This joint sub-committee considers that exhibitors could not have more favourable conditions for demonstrating the merit of their exhibits than those which this new arrangement will afford, and that, at the same time, in the way of instruction by such demonstrations the visiting public will be greatly benefited.

I am, Sir, yours faithfully,

BOVERTON REDWOOD,
Chairman, Chemical Industries Committee.

Board of Trade, Westminster, S.W., Feb. 2nd, 1911.

## TUBERCULOSIS AND STATE INTERVENTION.

*To the Editor of* THE LANCET.

SIR,—Referring to further correspondence under this head in your issue of Jan. 28th will you allow us to add that the purpose of our recent letter to THE LANCET, which was to correct a misleading impression which seemed current—namely, that the Edinburgh Conference on Tuberculosis favoured the principle of separate legislation directed especially against tuberculosis—has been achieved. A motion in favour of such legislation was, indeed, submitted to the meeting, but was lost. The resolution which was passed by the Conference was definitely limited to the question of including tuberculosis in the proposed scheme of invalid insurance. Your special Sanitary Commissioner clearly grasped the distinction as shown by the report in your columns.—We are, Sir, yours faithfully,

W. LESLIE LYALL, M.B. } Joint Honorary
JAMES MILLER, M.D. } Secretaries.

Edinburgh, Jan. 30th, 1911.

## THE NOMENCLATURE OF THE SUPRARENAL PRINCIPLE.

*To the Editor of* THE LANCET.

SIR,—In THE LANCET of Sept. 3rd, 1910. p. 778, you printed a short paragraph entitled "New Words." You commented upon the supplement of four pages to the Standard Dictionary of the English Language which you had received from Messrs. Funk and Wagnalls, and you mentioned that the word adrenalin had been included in that supplement to the well-known dictionary. It may be interesting to quote the full definition there given. It is as follows:—

Adrenalin. *Chem.* A hemostatic astringent principle of the suprarenal gland: the most powerful astringent known. (Coined by Dr. Norton L. Wilson, Nov., 1900.)

I am, Sir, yours faithfully,

London, Jan. 31st, 1911. INTERESTED.

TRAINED NURSES' ANNUITY FUND.—Her Majesty Queen Alexandra has approved of the suggestion that the surplus of £90 remaining after the purchase by the members of the Territorial Nursing Service of a cross for the tomb of King Edward VII. shall form the nucleus of an additional annuity for disabled trained nurses. The annuity will be called the King Edward VII. Memorial Annuity and the Council of the Trained Nurses' Annuity Fund has issued an appeal for subscriptions to make the amount up to £900, the sum required to endow an annuity of 10*s.* per week. Contributions may be sent to the Bankers, Messrs. Coutts and Co., 440, Strand, London, or to the honorary secretary, Dr. A. Ogier Ward, 73, Cheapside, London, E.C.

## THE HOUSING PROBLEM IN SOUTH WALES.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(*Concluded from p. 334.*)

### *The Swansea Strand.*

THE problem at Swansea is similar in most details to that of Merthyr Tydfil. There is in both towns the sudden augmentation of population due to the rapid and recent developments of the mining and metallurgic industries. But at Swansea we find further complications arising from the growth of the port, with its ever-increasing fleet of ships that bring ore and take away coal, attract poor dockers in quest of work, and land sailors in search of dissipation. This necessitates such districts as the Swansea Strand, which Mr. George R. Sims, in his little book entitled "Human Wales," describes as a district of difficulties built by "the river of sin upon the strand of shame," where there are girls of 20 who are old already. As a matter of fact, however, it is very fortunate for the town as a whole that the more vicious and disreputable elements of the population should concentrate in a particular district. Of this Swansea has had recent experience. Some labour members of the borough council of Swansea complained that too much care was taken in the choice of tenants for the houses built by the corporation, and that it was precisely for the poorest and the most unfortunate that the houses were intended. The result was that several persons gained admittance into corporation dwellings who were poor only in manners and morals. A little experience of this sort soon brought about a reaction, and now every effort is made to secure only respectable tenants for the corporation houses. At the same time, preference is shown for a tenant who comes from one of the congested districts.

The Strand is a main street facing some of the docks. There are a few common lodging-houses in this thoroughfare and many courts behind on rising ground. The common lodging-houses are only overcrowded on Saturdays in the winter. The tramp is then driven in by stress of weather. The cottages in the courts are often overcrowded, and here and there the closets get out of order and require very frequent inspection so that the flushing cisterns should act properly. Naturally, I made a point of visiting these places, notably Neptune-court, Bargeman's-row, Jones'-court, and the neighbouring courts and alleys. Here I saw some houses built on terraces cut out of the hillside, so that the backs were close to the bare earth, which rose up perpendicularly to the height of the first floor back windows, leaving a space of only five feet between the house and the earth. Some cottages were so small that there was no room for a proper staircase, and the steps from the living-room on the ground floor to the sleeping-room above were so precipitous that they seemed more like ladders. Elsewhere there was a row of one-roomed cottages so small that the wall from the earth to the eaves of the roof was not six feet high. But they gave on to an open space and were swept on all sides by fresh air.

### *Increase in Trade, Overcrowding, and Distress.*

Swansea is fortunate in possessing a large quantity of land so that the corporation can build without having to purchase building sites. This is the more welcome, as there is a most pressing demand for houses at rents varying from 6*s.* to 7*s.* 6*d.* a week. Houses at 12*s.* 6*d.* could more easily be obtained, but this is too much for a workman, and means that he would have to divide the house with another family and then there would be overcrowding. It was some 15 years ago that a very bitter cry was raised for better housing, and after a good deal of hesitation the corporation had to undertake the work of housing. Its first experiments were not all successful. In one case the houses built were too good for the neighbourhood. Those who lived near could not pay the rent and those who lived elsewhere would not take up their quarters in such poor surroundings. So there is a slight loss on this property, but all the other schemes are self-supporting. Altogether, the town has built 207 houses and it is inviting tenders for the construction of 103 more. They are to be built in central parts of the town where they will be far more useful than those in suburbs which the workers have difficulty in reaching, especially if they are employed in the docks. Many tenants absolutely

refuse better houses for a lower price if they are at some distance from the centre. Thus we still hear of families with four and five children living in two rooms with hardly 100 cubic feet of space per head. A town councillor assured me there were 400 families thus crowded together, and mentioned the case of a man living with his wife and mother and 13 children in one room. Another family was lodged over an evil-smelling stable, and their food was always covered with flies. All this, of course, is absolutely illegal, but till many more better houses are built the law cannot be enforced. Then there comes the great difficulty of paying the rent. The fact that many industries are very prosperous does not lessen this trouble. To some extent as a consequence of the McKinley tariff the growth of trade in the closing decade of the nineteenth century was equal to only 5 per cent. But now other outlets in China, Japan, and various parts of the world have been found, so that the increase of trade during the first 10 years of this century is equal to 15 per cent. The anthracite trade also has grown. As a case in point the story is told of a laundry-woman who invested £200 30 years ago in tin-plate works; her share is now worth £40,000, the profits having been allowed to accumulate. Works started not so long ago with £10,000 are worth half a million, and all this bears very directly on the housing question, for it is these tales of gold that draw people to Swansea and account for the overcrowding. It is also a melancholy satire on our modern civilisation that where there is the most wealth there also will be found the direst poverty. Thus at Swansea, according to the *Labour Gazette*, there are more men in proportion inscribed on the distress register than in other large towns of the kingdom. To cope with this excessive unemployment the town council have at different times engaged as many workers as possible, paying them the full trade-union wage, but for only three or four days a week so as to be able to divide the work up among a greater number of applicants. By this means they kept some thousands off the poor rates. Last year the council spent £4290 in giving 12½ days' work at trade-union wages to the unemployed. Also they have introduced the fair contract clause for all contracts for public works, but the Harbour Trust is not considered a public body, so it could not be enforced there. However, it will be seen that in so far as the corporation is able to raise the scale of wages it has endeavoured to do so, and this is not merely an important but a fundamental consideration when dealing with the housing question. It is not necessary to be wealthy to have a healthy home, but there is a poverty-line below which healthy conditions become absolutely impossible. Consequently, a minimum living wage becomes an integral part of the housing question. This, it seems, is fairly well understood by the Swansea town council. It accounts for the tenderness shown towards the poor dwellers of insanitary houses. Thus, in the last annual report issued by the medical officer of health, 45 houses are reported as "permanently unfit." Of these, only three have been demolished, four closed, two are vacant, one is repaired. Seven are to be closed and the tenants are under notice to quit, but in the majority of cases nothing had been done when the report was written.

### *Gardens Converted into Slums.*

Among houses recognised as unfit and which were nevertheless to be tolerated for the time being were six houses in York-court and four houses in Dewsbury-court. These dwellings form part of a small slum area in the very heart of the town, where I at last found conditions similar to what prevails in large towns like London, Manchester, and other industrial centres not built on a mountainous site. We have here a good illustration of what did happen and what would still occur if there were no law and no authority to check private speculation. The accompanying plan shows six middle-class three-storeyed houses giving on to York-street. Behind each house there used to be a long strip of garden. When, however, the demand for workmen's cottages became very pressing it occurred to the owner of one of these houses to reduce the size of his ground-floor parlour so as to cut a passage under and through his dwelling from the street to the garden behind. Here he destroyed the healthy air-space by building six little cottages, and instead of a garden we have Rosser-court. The entrance passage is only 2 feet 9 inches wide, 7 feet high, and 28 feet long. As for the cottages, they have only 4 feet 9 inches of space in front to the garden wall of the next house. Here, fortunately, the owner did not care to follow the example of his neighbours. He did not cut a passage through his house and convert his garden into a slum. But there is next door York-court, where the covered entrance passage is 42 feet long, 7 feet high, and 2 feet 9 inches wide. The court beyond is only 8 feet wide for two rows of cottages facing each other, though they have no accessible space behind, and on one side the houses are back-to-back with those of Dewsbury-court. The smallest of these houses containing only two rooms is let for 4*s.* a week. Dewsbury-court is even worse. The entrance passage is 30 feet long, and the dimensions are the same as the other passages; but the court itself is narrower still. Though there is no air-space behind the houses, the court in front is only 4 feet wide; but in exchange for these abominable conditions one exceptionally small dwelling can be obtained for 3*s.* 6*d.* per week. The back wall of the houses of Bennett-court reaches the height of the upper windows of the front of the houses in Dewsbury-court, and thus effectively blocks out the direct rays of sunlight. Here, then, we have extreme poverty, overcrowding, insufficient ventilation indoors, and not enough air-space and light out of doors. Bennett-court is better, for, though it is also only 4 feet wide, there are no buildings on the other side of the wall that faces the houses. Obviously, all these courts should be condemned; indeed, many of the houses have been condemned, but they are still full of people simply because there is no place to which they can go. They can only afford the very lowest rent, and they are the more anxious to live near their work as there are no cheap means of communication with the outlying districts. The few tramways in Swansea make exorbitant charges; they are at least twice as dear as the London tramways, and four or five times dearer than those of Marseilles, where the most distant suburbs can be reached for the uniform charge of 10 centimes, or 1*d.* The Marseilles system is the true system to prevent congestion. Those who live close to the centre have to pay just as much as those whose homes are five or six miles away in the open country, and in either case it is only 1*d.*

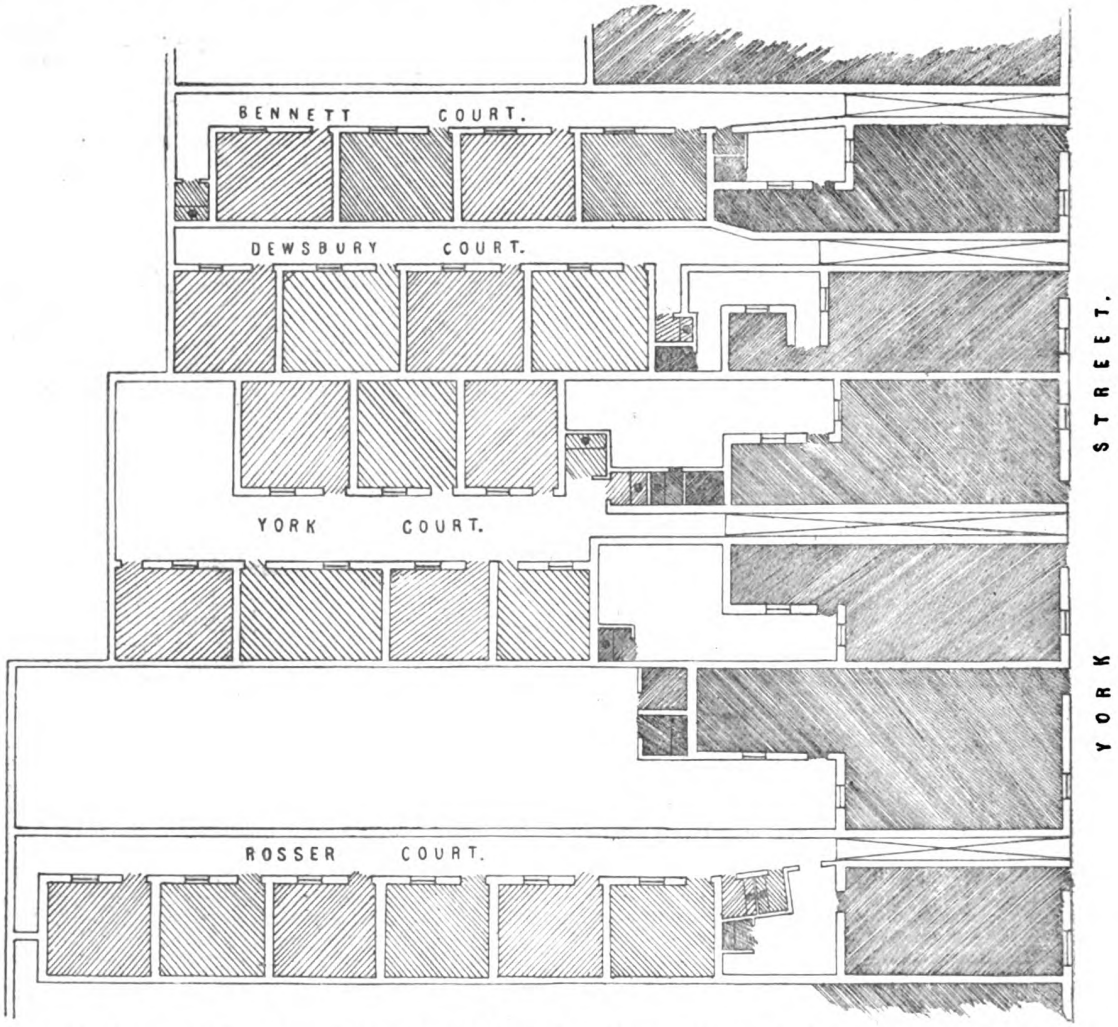
### *Slumming in Swansea.*

After this York-street area, perhaps Tontine-court and Swan-court, its immediate neighbours, have acquired the worst reputation. The trouble here is also due to the fact that the houses are back-to-back and that other cottages have been built in the backyards, thus materially reducing the space behind. But these houses are only one storey high and the air and sunlight can reach them, and they are much better exposed in this respect than the tenements in the backyards of old houses six and seven storeys high in Edinburgh or Glasgow. Some of these miserable dwellings were kept very clean. One back room in Tontine-court was occupied at a rent of 2*s.* a week by a single and aged woman. It was a small room, but quite big enough for one person. Everything was very clean, and there was a cosy, comfortable look about the place with its bright fire on one side, the neat bed on the other side, half concealed by the open door. The chairs, table, and knick-knacks were all well cleaned and shining brightly with the glow from the abundant supply of coal piled up in the grate. What would the Parisian poor give for such a fire and for a room of that size rented at only 2*s.* a week. They have to pay £2 a ton for coal, wood is much dearer, and the Paris winter is much colder than the winter at Swansea. Nevertheless, the sanitary authorities are quite justified in proclaiming as "permanently unfit" five houses in Tontine-court and four houses in Swan-court; though after visiting these dwellings I also think that the inhabitants may as well be left in quiet occupation till such time as there are better houses available.

From these two courts I went to many poor, wretched places, including the blood-red, sinister-looking little houses of Green-row, where the pavement is as dilapidated as the appearance of the poor out-of-work women who loiter about upon it. One or two houses have actually been closed in this street, while close at hand back-to-back houses were abolished in Green Hill-street. It used to be a thoroughly bad locality. The death-rate of this district for the five years ending 1902 was 31·4 per 1000. Since then several of the courts have been entirely pulled down and the district has been much improved. Still, close by, in Jockey-street, I was shown a four-roomed cottage and was told

that a man and wife and six children had been driven out of this dwelling by the sanitary authority because it was already occupied by the man's father and mother, a married daughter, her husband, and three children! Union-court, High-street, overlooks the back of the Strand houses, and here and in Crab Tree-court there are some very narrow, wretched places. The cottages, though they have but one bedroom, let at 4*s.* a week, and there are some people who have lived in them all their lives. The ceilings are low, the room dark inside, but the closets and drains are all outside, the courts are covered with concrete, kept fairly dry and clean, and, better than all, they are on the hillside, with the open sea just in front. Thus three is plenty of pure salt air conveying vigour and health to these poor slum dwellers. But the most picturesque, the smallest of all dwellings, are the little two-roomed cottages perched on the ledge of the rock in front of the old castle wall. They must be some centuries old, for no such thick walls are now built. The room upstairs is so small that it holds two beds only on condition of packing them so close together that it is difficult to pass between. The cottages are most miserable because they are so small and dilapidated. Like many other dwellings, they have been condemned, only nothing is done because there is no other place available for the inhabitants.

In conclusion to this brief contribution to the great subject of the housing problem in Wales, it should be very clearly said that the facts of the case are frankly acknowledged by the authorities. They fully recognise the overcrowding and the insanitary conditions. They have even officially condemned a considerable number of houses, but they hesitate to throw the inhabitants out into the street, knowing full well that there is no better accommodation available. Therefore more houses must be built, and this at the utmost speed. The authorities can borrow money for such purposes at 3½ per cent. interest, but private enterprise can borrow money at 4 per cent., so there is not the difference in the cost of a loan there used to be. Nevertheless, private enterprise is not dealing with the question. The owners of great ironworks have built rows of cottages for their own workmen, but these are not of general use; they will not, for instance, lodge the great number of workmen attracted by the building of the new St. Thomas dock. The corporation is almost alone in dealing with the housing problem, but how are houses to be provided at cheap enough rents, particularly as the rating, including the water-rate, amounts to about 10*s.* in the £? Most of the corporation's houses occupy beautiful healthy sites on the hill-side with magnificent views of the open sea. They have baths and better sanitation than has ever been provided before, but



*Courts, &c., in Swansea.*—Rosser-court: Entrance from York-street through covered passage 28 feet long, 7 feet high, and 2 feet 9 inches wide; court is 4 feet 9 inches wide from front of houses to garden wall of the next house in York-street. York-court: Entrance from York-street through covered passage 42 feet long, 7 feet high, and 2 feet 9 inches wide; court is 8 feet wide. Dewsbury-court: Entrance from York-street through covered passage 30 feet long, 7 feet high, and 2 feet 9 inches wide; court is 4 feet wide. Bennett-court: Entrance from York-street through covered passage 27 feet long, 7 feet high, and 2 feet 9 inches wide; court is 4 feet wide. The light shading shows how back gardens have been converted into crowded narrow courts with back-to-back houses.

workmen wearied by a day's toil object to climb up a steep hill to reach their home. A funicular railway is much needed to open out the higher ground, and thus the magnificent amphitheatre of hills that overlook Swansea and face the sea could be covered with numerous dwellings reared on an ideal site. The soil is clay loam, with more loam than clay, and is considered good building soil. 500 new houses would let at once, and therefore, it seems to me, they should be constructed without delay. Whether this is done by the corporation or by private enterprise the essential point is that it should be done at once, and that the plans and the execution of the plans should be fully controlled and approved by the sanitary authorities. Delay is the more intolerable, as this is a safe undertaking, and with ordinary prudence of management will yield at least a small profit.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

*The University.*

THE Chancellor of the University, Mr. Joseph Chamberlain, has addressed a letter to the Lord Mayor, fully setting out the financial position of the University, and urging its claim for a further grant from the city council equal to a half-penny rate. The additional Treasury aid promised by the Chancellor of the Exchequer will be, to a great extent, contingent on an increased contribution from local bodies. At present the University receives the proceeds of a half-penny rate from the city which amounts to £6134; the county councils of Staffordshire and Worcestershire each contribute £500. The Chancellor's letter is still under the consideration of the city council.

*Epileptic Children in Birmingham.*

The special schools subcommittee of the Birmingham education committee has had under consideration the question of the education of epileptic children. Full inquiries have been made from the head teachers and school attendance officers with a view to ascertaining the total number of children suffering from epilepsy, either in a mild or severe form. The medical superintendent, Dr. G. A. Auden, has examined all the children whose names were received, with the result that 129 have been classified as actually suffering from epilepsy. In addition, 15 children are being maintained in residential schools fer epileptics in different parts of the country. In a report by Dr. Auden and Mrs. Pinsent the children have been divided into three main groups. Class 1 contains those needing institutional care and treatment. For these it is recommended that arrangements should be made for their education in a children's department at the Monyhull Colony, near King's Heath, under powers to be conferred by the Poor-law clauses of the Greater Birmingham Bill. There are 48 children in this class, of whom 15 are already in residential schools for epileptics. Class 2 consists—1. Of children in whom mental defect is combined with epilepsy, and for whom training in a day school is possible for the present. It is recommended that these should be admitted to the special schools for the mentally defective as soon as possible. It is proposed to provide at each of the three special schools a specially constructed couch on which the children can be removed from the class-rooms, and also a moveable screen to surround it, so that children may lie down when having a fit and recovering from its effects. The number of children in this class is 42, 23 of whom already attend special day schools. 2. Epileptic children who are only capable of being trained in residential schools for the mentally defective. These the subcommittee recommends shall, when the Greater Birmingham Bill has passed, be included in the number of cases of mentally defective children for whose provision at Monyhull the board of guardians and the education committee are already trying to arrange. 3. Those whose degree of defect renders imbecile asylum treatment and training advisable. It is proposed to add these cases to the list of idiots and imbeciles already kept and to confer with the guardians and the asylums committee as to the desirability of making further provision. The number of children in this class is 55. Class 3. Epileptic children suitable for attendance at ordinary elementary schools—i.e., those who have had but one or two fits, and who should be kept under observation, and those whose history and condition show that cure is highly probable. The subcommittee has recommended the elementary education committee to ask the medical superintendent to devise a scheme, whereby he will receive a report on these children and if necessary re-examine them at least every six months (or more frequently if desirable). The number of children so classified is 39.

*Health of Handsworth.*

The medical officer of health of Handsworth (Dr. W. Sisam) has presented a preliminary report to the health committee on the vital statistics for 1910. The birth-rate was 19·4 per 1000, the death-rate 8·8, and the zymotic death-rate 0·30 per 1000, all these being the lowest figures on record. The infantile mortality equalled 79 per 1000 births, this also constituting a record for the district. For the first time no death from diphtheria was recorded, and for the first time since 1875 no death from measles. Scarlet fever in a mild form was prevalent, but on the whole 1910 was decidedly the healthiest year ever experienced in Handsworth.

## NEWCASTLE-ON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

*Report of the Medical Officer of the County of Durham on the Prevention of Pulmonary Consumption, with Special Reference to Sanatorium Treatment.*

Dr. T. Eustace Hill, the county medical officer, has prepared a report on the above subject for the county council of Durham. After dealing briefly with the causes of phthisis and the modes of infection, he passes on to a consideration of the mortality in the county, where the deaths from phthisis annually exceed 800, and those from other forms of tuberculosis number at least 600, and he estimates that there are certainly more than 4000 persons in the county suffering from tuberculosis of the lungs. He gives tables to show a decline in the mortality from phthisis since 1892 of over 40 per cent., though there has not been so marked a fall in the deaths from other forms of tubercle which especially affect young children. He considers that the replacement of breast-feeding of infants by artificial feeding is responsible for the continued height of the infantile mortality, in view of the opportunities for infection by the milk of tuberculous cows. He points out that the marked decline in the general mortality has not been occasioned by any special measures taken to combat the disease, but is rather the result of generally improved hygienic measures in the way of sanitation, drainage, lighting, ventilation, &c., and also increasing temperance and greater attention to personal hygiene. Passing on to direct measures in the way of sanatorium treatment, he considers that while such measures have done good it must be admitted that the percentage of patients so treated who have been permanently cured is not so large as was at first expected—for two reasons, firstly, many were suffering from too advanced disease, and secondly because of the inability or unwillingness of the patients to continue the sanatorium habits when they reached home. He, nevertheless, has a great belief in the educational value of such institutions, and is of the opinion that the establishment of a county sanatorium for the treatment of curable cases is desirable, but the selection of such cases will be difficult unless the notification of phthisis is made compulsory. Voluntary notification had been tried in some parts of the county for some years, and is practically useless, and he therefore advocates compulsory notification, and believes that the intelligent use of such information would be of great value and should entail no hardships on the individual, because it "enables friendly supervision to be exercised over the patients, early selection to be made of cases suitable for sanatorium treatment, precautionary measures to be taken in infected dwellings against the spread of the disease, and the dissemination of suitable literature in the proper quarters, and frequently it results in the detection of early cases in the families of notified cases, which otherwise would escape notification until the disease had become too advanced to be cured." His report becomes very interesting when he deals with the practical difficulties of the establishment of a county sanatorium. There are two ways of doing this: firstly, by the

district sanitary authorities combining under the Act of 1875; and secondly, by the county council constituting the county, or part of the county, as a hospital district under the Isolation Hospitals Act. To the former of the two methods there are practical difficulties, and it appears to Dr. Hill that the cost of erecting and furnishing such a sanatorium should be a charge on the county rate. But legal opinion has been taken that the constitution of the whole of the county as a hospital district for phthisis is not legally practicable, because certain districts have already been constituted hospital districts for certain infectious diseases, and there is no power to include such districts in a larger hospital district for other purposes. So that several urban districts (with a population of 145,000) could not be included, and, moreover, the non-county boroughs (with a population of 180,000) could not also be included save with the consent of their corporations. So that unless some mutual agreement could be made with the local authorities a population of about 330,000 out of a total or 900,000 would not be able to participate in the scheme. He thinks, however, that the majority of local authorities might be induced to join, and a conference of county, borough, and district representatives is advocated. The cost of establishing such a sanatorium of 100 beds (50 permanent and 50 temporary) he estimates might be a charge on the county rate of less than 1*d.* in the £, or if the money were borrowed over 30 years at 3½ per cent. the charge on the rate would be less than one-twentieth of a penny. The estimated cost of maintaining the institution is about £6500 yearly, and for this sum the district authorities would be responsible. The way to deal with advanced cases he emphasises as specially important. In the case of those having Poor-law relief provision should be made by the guardians, especially when it is remembered that in the majority of such cases the necessity for relief has been occasioned by the infection of the breadwinner of the family. The isolation of such patients is necessary for the public health, and the expense ought reasonably to be borne by the district. He points out that at present in two districts in Durham the small-pox hospitals are being utilised for tuberculosis, and thinks that more use might be made of such buildings. Other points to be specially noted in the report are the method of following up notified cases and their families by the medical officers and the sanitary inspectors, when in conjunction with the medical attendant the determination is come to with regard to those cases suitable for sanatorium treatment. A practitioner suggested to Dr. Hill that in each village or town one or two houses might be obtained and furnished reasonably, so that consumptives returning from sanatoriums might be able to continue such treatment, and this is a matter well worth consideration. Finally, Dr. Hill urges the need for more legislation to deal with the inspection of cows and dairies and greater supervision over the sale of milk. The conclusions of an interesting report are: (1) Sanatorium treatment for suitable cases; (2) provision of accommodation for advanced cases which are a danger to public health; (3) compulsory notification of cases of tuberculosis of the lungs; (4) an adequate staff to supervise and assist the patients and to deal with sanitary defects; (5) provision of houses for returned sanatorium cases; and (6) prevention of the sale of milk from tuberculous cows.

*Clinical Society, Newcastle-on-Tyne.*

On Jan. 25th Dr. J. S. Risien Russell delivered the annual address to the society, choosing as his subject "Important Problems in the Diagnosis of Diseases of the Nervous System." The meeting was well attended. In the evening the annual dinner took place, the President, Dr. E. Napier Burnett, being in the chair to preside over a company of 110. The President proposed the health of "The Guest," suitably replied to by Dr. Risien Russell; Dr. Byrom Bramwell, who as an old Newcastle medical man met with a great reception, proposed "The Clinical Society," which was replied to by the honorary treasurer, Dr. D. Wells Patterson; while the third toast, that of "The Visitors," was in the hands of Sir Thomas Oliver, and responded to by Mr. W. H. Hadow, Mus. Doc., the Principal of the Armstrong College, Newcastle-on-Tyne, who dealt in a racy fashion with the medical profession as viewed through the eyes of a layman.——On Feb. 2nd the usual ordinary meeting of the society was held. The early part of the evening was devoted to an exhibition of and discussion on pathological specimens shown, and later Dr. C. O. Hawthorne of London read a paper on the Interpretation of Some Blood Pressure and Pulse Tracings. There were some 40 members present. At the conclusion Dr. David Drummond joined in the discussion and moved a vote of thanks to Dr. Hawthorne, which was duly carried amid applause.

Feb. 6th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

*Presentation to Emeritus Professor John Chiene, C.B.*

THE presentation to Professor John Chiene, C.B., of his portrait by Mr. Fiddes Watt, A.R.S.A., took place on Jan. 31st in the hall of the Royal College of Surgeons, Principal Sir William Turner, K.C.B., presiding. Among the large gathering of Professor Chiene's friends were Lord Stormonth Darling, Sir J. H. A. Macdonald, Lord Ardwall, Lord Salvesen, Professor Sir Thomas Fraser, Sir Alexander Christison, Sir Alexander R. Simpson, Sir James Russell, Professor Sir Ludovic Grant, Bart., with other members of the Senatus of the University and of the medical and legal professions in Edinburgh. The secretaries of the presentation committee were Mr. L. A. Guthrie and Mr. David, Wallace, C.M.G. Mr. Guthrie said that there were 393 subscribers to the presentation, the total amount collected from many parts of the world, being £724 5*s.* 6*d.* Many letters had been received from Professor Chiene's friends, especially from old students, expressing the esteem and affection in which he was held. Sir William Turner announced that after the artist had received his fee a sum of money remained which it was proposed to hand to the University to provide a "Chiene medal," accompanied by a cheque, for excellence in surgery. Lord Ardwall, in making the presentation, spoke appreciatively of Professor Chiene's work as a teacher in the Edinburgh School of Medicine. His lectures were marked by originality, enthusiasm, and a good deal of pawky Scottish humour. Professor Chiene had been the first in this country to institute a bacteriological laboratory in connexion with a chair of surgery. As a surgeon his name was inseparably connected with the revolution in surgery introduced by Lord Lister, whose right-hand man he became. He distinguished himself by his services in South Africa, services which had been properly, if not adequately, rewarded with a Companionship of the Bath. They hoped he would accept the picture as a token of their esteem for him as a distinguished surgeon, a great teacher, and a true and trusted friend. Sir William Turner said he had known Professor Chiene 51 years, and he corroborated the sentiments Lord Ardwall had expressed. Professor Chiene, in his own name and that of his wife, thanked all his friends for the honour they had done him. He referred to his student days and to the good fortune he had had as a young man in the friends he had made, mentioning especially John Goodsir, Peter Guthrie Tait, and John Brown. Goodsir had sent him to Syme, who introduced him to Lister. A vote of thanks was given to the artist, Mr. Fiddes Watt, for the excellent portrait, which is three-quarter length and a characteristic likeness of Professor Chiene, who is represented holding in his hand the portfolio which he was accustomed to carry when going to and from the University.

*Plague in Manchuria and Scottish Missionaries.*

News by cable has been received in Edinburgh of the death from plague in Moukden, Manchuria, of Arthur Frame Jackson, B.C., M.B. Cantab., a missionary of the United Free Church of Scotland. Dr. Jackson, who held the diploma of the Liverpool School of Tropical Medicine, was appointed in 1910 as a medical missionary to Moukden to assist Mr. D. Christie in his scheme of establishing a medical college in that city. His personal character and professional abilities justified the highest expectations as to his future work.

*Death of a Military Surgeon in Edinburgh.*

The death occurred at his residence in Edinburgh, on Jan. 23rd, of Brigadier-Surgeon-Lieutenant-Colonel David Renton, A.M.S., in his seventy-fourth year. Colonel Renton was educated at Loretto School and at Edinburgh University. When 24 years of age he joined the 15th Hussars. After serving five years in India he took part in 1879 in the

Zulu war, for which he received a medal. He also served in the Transvaal war in the "eighties." On retiring from active service in 1888 he became barrister-at-law of the Inner Temple. He is survived by his widow, two sons, and three daughters.

*Inter-Universities Conference at Perth.*

On Jan. 31st representatives of the general councils of the four Scottish universities met at Perth to consider the reform of the preliminary examinations of the Scottish universities. They recommended that the preliminary examination in science should be made the same as that for arts, and that in the case of medicine the standard of entrance should be raised to that of arts and science as soon as practicable. It was further agreed to recommend that a new entrance board be constituted instead of the present joint board.

*Death of Dr. William Patrick.*

The death of Dr. William Patrick, who has been in practice in the East-end of Glasgow for the past 49 years, occurred last week at his residence in the Bridgeton district of the city. Dr. Patrick was born in Bridgeton, and in that district he practised throughout his life. He started as a Licentiate of the Faculty of Physicians and Surgeons, Glasgow, but a few years later he graduated as M.D. at the University of his native city. Throughout his life he was keenly interested in medical affairs and took an active part in various medical societies. He held the appointment of certifying factory surgeon for the south-eastern district of Glasgow, a Government appointment in which he took great interest, for it brought him into contact with many employees, by whom he was held in the highest esteem, while he was concerned largely with the health of young workers, for whose welfare he was solicitous. His fatal illness developed rapidly, for his last appearance in public was at the dinner to Sir David C. McVail so recently as Jan. 20th. Both in the profession and in the city at large Dr. Patrick's death has given rise to a sense of widespread loss and regret. He leaves a widow, five daughters, and two sons who are members of the medical profession.

*North of England Graduates of Glasgow University.*

The annual dinner of the North of England Glasgow University Club was held at Newcastle a few days ago. Dr. James Drummond (South Shields) presided, and the guests of the evening were the Rev. George Adam Smith, Principal of Aberdeen University, and Dr. C. O. Hawthorne, London. Dr. Samson Gemmell, Professor of Medicine at the University of Glasgow, was unable to be present in consequence of a chill.

*Treatment of Sick Poor.*

The quarterly meeting of the Association of Inspectors of Poor for the Counties of Aberdeen, Kincardine, and Banff was held on Jan. 28th, when the report, noted below, on the treatment of sick poor was considered. The parishes represented by the association had been asked for a statement regarding the following remarks in the report of the Royal Commission on the Poor Laws (p. 260):—

> When we realise that outside Glasgow, the Poor Law accommodation for the sick poor is nowhere anything but the general mixed poorhouse, which was never intended to serve as an hospital ..... it is difficult to believe that we are speaking of a civilised country in the twentieth century.

Sixty-six years ago it seems to have been recognised that the poorhouse should concern itself with the sick poor, for the statute reads—

> And be it enacted that in all cases in which poorhouses shall be erected or enlarged or altered, under the provisions of this Act, there shall be proper and sufficient arrangements made for dispensing and supplying medicines to the sick poor (Poor Law Act, 1846, Section 66).

But, disregarding any real or seeming discrepancy between the two extracts, it was thought that, leaving out of the question the facts of the case 66 years ago and taking rather into consideration what is now the best thing for the sick poor, it would be useful if the association were to inquire whether the statement made in the report of the Royal Commission is a fair and true statement, or whether, in other words, it is the case that no parish in Scotland, excepting Glasgow, has any accommodation for its sick poor outside the poorhouse. With this in view, therefore, the following questions were sent to the different parishes:—

1. Have you a local or district hospital to which sick poor chargeable to the parish can be sent, or are they sent to the Royal Infirmary when they cannot be treated in their own homes?
2. If a local or district hospital, name and situation?
3. Have your outside poor the services of a district nurse?
4. Is it usual when your registered poor are sick to send them to the poorhouse?

One hundred parishes were communicated with, and most of them have replied to the queries as follows: 1. 45 parishes sent their sick poor to the Royal Infirmaries in Aberdeen and Montrose when they could not be treated in their own homes, parish council patients being received in the former institution at 3*s.* per day; 14 parishes arranged for their sick in their own homes or by boarding them out and providing nursing; 15 parishes had suitably equipped local hospitals of their own, while a further number had specially provided sick accommodation within the parish. 2. Of the local hospitals good examples are: Chalmers' Hospital, Banff; Turner Memorial Hospital, Keith; Huntly Jubilee Hospital; Rose-Innes Cottage Hospital, Aberchirder; and the Thomas Walker Hospital, Fraserburgh. These freely admit all classes, and the board of management of some of them is largely composed of parish council members. 3. 34 parishes have district nurses for their sick poor. 4. 74 parishes never send their sick to a poorhouse; 10 state that on rare occasions they have sent cases to the sick wards of a poorhouse, mostly chronic cases which could neither be benefited by hospital treatment nor be nursed at home, and 8 parishes state that they provided for their sick in the poorhouse hospital at Oldmill, Aberdeen, which was an excellent hospital with dispensary, although connected with the poorhouse. The only question now left to dispose of is as to whether institutions such as are recommended by the Commission would be preferable in point of treatment, &c., to institutions such as the Aberdeen Royal Infirmary, the answer to which seems self-evident. With regard to the smaller local hospitals, those are generally regarded with exceptional favour by the poor, as all classes make use of them without distinction, and in general the arrangements made by the different parishes for their sick seem perfectly adequate.

*Elginshire Medical Officership.*

The Secondary Education Committee of Elginshire has decided that the medical officer of the county shall, in addition to his other work, undertake the duties of inspecting the school children throughout the county. The salary for the combined duties, as proposed, is £550.

*Death of Dr. William Mackintosh at Montrose.*

Dr. William Mackintosh, who last summer retired from Stirling, where he had been in practice for 20 years, and took up residence near Montrose, was discovered dead in his bath on Jan. 28th. Heart failure was the cause of death. Dr. Mackintosh was 55 years of age, and leaves a widow and three children.

## IRELAND.

**(FROM OUR OWN CORRESPONDENTS.)**

*Alleged Bribery at a Medical Election.*

ON Feb. 3rd the Court of King's Bench granted a conditional order of *mandamus* on the motion of the Local Government Board directed against the Scariff guardians, compelling them to proceed to the election of a dispensary medical officer of the Annacarriga district. The facts as stated by counsel, supported by an affidavit of the Secretary of the Local Government Board, were that on August 9th last there was an election for a medical officer for the Annacarriga dispensary district in the Scariff Union. There were two candidates, Mr. John Holmes and Mr. Henry M'Keogh. Mr. Holmes was elected by a majority of 48 votes to 20. Mr. M'Keogh applied to the Local Government Board to hold a sworn inquiry as to charges of bribery and corruption on the part of Mr. Holmes, the successful candidate. Sir J. Acheson M'Cullagh, the Local Government Board inspector, held an inquiry in Killaloe, and on consideration of the evidence the Local Government Board was of opinion that bribery was practised in connexion with the election on behalf of Mr. John Holmes with his full knowledge and authority; and thereupon the Board decided that it would not approve of his appointment. After further meetings and inquiries, the Local Government Board wrote on Nov. 12th still declining to sanction Mr. Holmes's appointment. At a meeting on Nov. 29th, the guardians considered

the attitude of the Local Government Board, and Mr. Holmes's solicitor appeared at the meeting and stated that the guardians should continue Mr. Holmes in office. A resolution was passed asking the Local Government Board to state its grounds of objection, and when this was done the letter of the Local Government Board was marked "read." On a subsequent letter being received from the Local Government Board stating that it would have to apply for a mandamus, Mr. Holmes offered to indemnify the guardians against any costs, in the event of the Local Government Board taking steps to enforce the terms of its letter. Instructions were given to have the necessary guarantee executed. The guardians had not appointed, and refused to appoint, a medical officer pursuant to the statute.

*Payment of Substitute for Infirmary Surgeon.*

On Feb. 1st the Court of King's Bench gave judgment regarding the liability of a county infirmary committee for the payment of a locum-tenent for the surgeon of the institution. Mr. N. Mayne, surgeon to the County Longford Infirmary, was obliged to attend the winter sessions of 1908 on a subpœna from the Crown. He appointed a substitute for the week of his absence, paying him a fee of 5 guineas, which he subsequently claimed from the committee. The latter repudiated responsibility and was sued by Mr. Mayne, the case causing an appeal to the King's Bench. No evidence was adduced as to usage or terms of appointment as regarded payment of a substitute. The court unanimously dismissed the case. It would appear as if the question had never arisen before in the case of an infirmary surgeon. In the Poor-law service a medical officer is considered to be disabled for duty by attendance on a subpœna, and his substitute is paid by the guardians, who in some cases are permitted to deduct the fee from the medical officer's salary.

*Mortality and Disease in Dublin.*

The death-rate in the city of Dublin for the week ending Jan. 28th, omitting the deaths in public institutions of persons admitted from without the city, reached the alarming figure of 29·4 per 1000 of the population. Of the total of 177 deaths, 26 were of infants under one year of age; 9 deaths were due to whooping-cough and 13 to pneumonia. There is a great deal of zymotic disease in the city at present, chiefly scarlet fever, diphtheria, and enteric fever.

*Irish Medical Schools and Graduates' Association and the Recent Action against Mr. Charles Ryall.*

The council of the Irish Medical Schools and Graduates' Association have taken the earliest opportunity of congratulating Mr. Charles Ryall, F.R.C.S. Eng., on the result of the recent trial. Referring to its triumphant issue for him they add:—

> We further desire to assure him that the complete vindication of his action in the case, the evidence in which only served to show the surgical skill that he displayed in saving his patient's life, has given this council much gratification, confirming the high esteem in which he is held by his professional brethren generally.

*Diphtheria in Dundalk.*

There has been a serious outbreak of diphtheria in Dundalk in the past few months. No less than 98 persons have been attacked, with fatal results in 12 cases.

*Royal Sanitary Institute Congress.*

At a meeting, held in the City Hall, Belfast, on Jan. 31st, a local committee was appointed to make the necessary arrangements for the reception of the Congress in July, with the Lord Mayor as chairman, Mr. H. J. Johns, J.P., city treasurer, as honorary local treasurer, and Mr. H. W. Bailie (medical officer of health), Mr. James Munce (assistant city surveyor), and Mr. J. G. Harris (assistant town clerk) as honorary secretaries.

*Health of Belfast.*

At the monthly meeting of the corporation held on Feb. 1st it was reported that between Dec. 18th, 1910, and Jan. 14th, 1911, there had been notified 130 cases of infectious diseases—i.e., 1 of typhus fever, 2 of typhoid fever, 87 of scarlet fever, 2 of puerperal fever, 25 of diphtheria, 1 of membranous croup, and 14 of erysipelas. 53 cases of pulmonary tuberculosis have also been notified. The satisfactory point about these returns is the fact that the number of cases of infectious disease notified is somewhat smaller than in the preceding four weeks (130 as against 170), though it is larger than in the corresponding four weeks of 1910 (105), this diminution applying to all the infectious diseases, the decrease being greatest in the case of scarlet fever (87 cases as compared with 119 in the preceding month), and it is specially gratifying to see the decrease in typhoid fever. As to pulmonary tuberculosis, there is a decrease as compared with the preceding month as well as the similar period of 1910, the numbers being respectively 53, 64, and 69. On the other hand, it must be remembered that the notification in four weeks of 87 cases of scarlet fever shows that the epidemic which has prevailed for such an unusually long period is still with us, and that—like the recent epidemics of measles and whooping-cough—it is simply wearing itself out, as similar outbreaks do in Belfast, because it has exhausted itself on all the susceptible patients for the time being. The large number of cases of pulmonary tuberculosis notified (53) also indicates how much has still to be done to cope with this most terrible disease. The death-rate was from all causes 16·4, while it was 6·0 from chest affections, and 0·4 from zymotic diseases.

*Newry Water-Supply.*

Newry, a leading town in the north of Ireland, is in anything but a satisfactory condition in regard to the very foundation of hygiene—its water-supply. At a meeting of the urban council of that place, held on Feb. 6th, the water caretaker reported that there was no water in the reservoir when he inspected it that morning. In the discussion which followed it came out that in some parts of Newry last week there had been no water for four days. The people at the high levels of the town had hardly any water, and at the Rathfriland Hill Hospital there had been no water for several days, a very serious matter in an institution of that kind. The surveyor thought there was a waste of water somewhere, and he proposed to look for the leakage. It was finally decided to send notices to householders cautioning them not to waste the water, and to postpone the inspection of the pipes until it was seen what action the Camlough water trustees would take regarding the installation of a water-meter. Surely it is high time that in a town of over 12,000 inhabitants steps were taken to secure a constant supply of pure water.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Radiography and Radioscopy of the Stomach.*

AT a meeting of the Société Médicale des Hôpitaux held on Jan. 20th M. Aubourg showed a number of radiographic representations of the stomach in various pathological conditions, such as air-swallowing, cancer of the orifices and the margins, ulceration, gastroptosis, and biloculation; these pictures had been taken in the course of radioscopic examinations made for the purpose of settling some typical detail or supplementing the clinical history. M. Aubourg said that rapid radiography and radioscopy were not to be regarded as essentially different methods of observation; they were, in fact, complementary to each other, and at the present day sketches of the radioscopic appearances were advantageously replaced by radiographic pictures which in their exactness and in the minuteness of their detail surpassed the fugitive images seen on the fluorescent screen. The interpretation of these pictures, however, required very great attention, a point which was exemplified by a case of biloculation of the stomach of which M. Aubourg gave particulars and showed five radiographic pictures taken at different periods of digestion. He said that examination of only one picture might have led to an error in diagnosis, but the exaggerated length of the peristaltic movement, the indentation of the sacculi, the presence of intestine between the pylorus and the liver, and the important symptom that the evacuation of the stomach was so slow as to be perceptible in the ninth hour of digestion, led to the diagnosis of biloculation. The radiological examination of the stomach should include not only the observation of its behaviour when food was introduced, but more especially the manner in which, and the time when it emptied itself, for these points were of great importance when there was a possibility of stenosis or biloculation.

*Actinomycosis.*

At a meeting of the Academy of Medicine held on Jan. 17th M. Schwartz described a case of actinomycosis in which the exciting cause of the lesion was found in contact with the diseased part. The patient was a man, 71 years of age, who suffered from a swollen condition of the left cheek. Six months previously, when sleeping on grass, he had felt a pricking sensation at the place, but supposed that it was caused by an insect. After this there was a swelling which increased from day to day, and he consulted M. Schwartz, who excised the swelling on the supposition that it was a sebaceous cyst. It contained a thick yellowish liquid, in which yellow granules and a portion of an ear of corn were found, and the diagnosis of actinomycosis was confirmed by means of the microscope.

*Treatment of Retroflexions of the Uterus.*

At a meeting of the Society of Paris Surgeons held on Jan. 13th M. Cazin said that all retroflexions of the uterus ought to be treated when the menopause was not due to occur for a considerable time. He had employed in succession Alexander's operation, hysteropexy, and the intraparietal fixation of the ligaments of Doléris. He preferred the method last mentioned, for it possessed the advantages of both hysteropexy and Alexander's operation without their inconveniences.

*Treatment of Enteritis in Suckling Infants.*

Speaking at the Biological Society on Jan. 21st M. Pierre Bonnier described seven cases of intestinal disorder, including enteritis, green diarrhœa, and athrepsia occurring in infants aged from 1 to 10 months. In every instance all, or the majority, of these symptoms disappeared in 24 hours after very gentle galvano-cauterisation of the inferior turbinated bones. The recovery of the functional equilibrium of the bulbar digestive centres resembled by its mode of action and its rapidity the effect produced on the respiratory centres by affusion on the cutaneous area of the trigeminus nerve in cases of asphyxia.

*Antityphoid Vaccination.*

A valuable report by Dr. Vincent on the subject of antityphoid vaccination occupied a great part of the meeting of the Academy of Medicine held on Jan. 24th. He said that up to the present time the antityphoid vaccines which had been most employed were bacterial vaccines—i.e., cultures of Eberth's bacilli killed by heat. In the course of years more than 100,000 persons had been successfully inoculated in the British, German, and American armies, more especially in the colonies to which troops were sent and in which typhoid fever was very common. Although antityphoid vaccination did not prevent the evolution of the disease in individuals who had become infected it greatly lessened the number of attacks, and those who fell ill suffered much less severely than unvaccinated persons. A single inoculation was not so protective as two or three inoculations. The duration of the immunity that was conferred appeared to be from one to four years. Whatever kind of vaccine was employed, the inoculation had always been found free from danger to the multitude of persons on whom it had been performed. Antityphoid inoculation would be very useful in the French army and navy, especially in Algeria, in Tunis, and in the colonies. It ought not to be performed except on perfectly healthy persons, free from any internal disease, and especially from tuberculosis. Except in cases of absolute necessity it was not advisable to inoculate debilitated or constitutionally delicate persons, for in them the reaction was liable to be too severe. It must also be remembered that for a period varying from one to three weeks after inoculation a person's vital resistance to the infection of typhoid fever was sometimes diminished, so that there might be, in fact, a temporary predisposition to contract the disease. Although this predisposition might be of little importance, there was reason to believe that the vaccinations ought not to be performed either in presence of an epidemic or on persons known to have been exposed to the infection of the disease within the previous three weeks. All newly inoculated persons ought to take the most careful precautions against infection with Eberth's bacillus; inoculation ought therefore to be absolutely forbidden in the case of those who had a prospect of an attack or were actually in the early stage of the disease. When the military or naval forces were being sent to places free from typhoid fever the inoculations might be performed on their arrival, but if the disease was either endemic or epidemic at the places in question the inoculations ought to be performed at least three weeks before arrival. In conclusion, Dr. Vincent said that antityphoid inoculation was to be recommended as a rational means of notably diminishing the frequency and the severity of typhoid fever.

*Removal of Foreign Bodies from the Bronchi and Œsophagus.*

At a meeting of the Société de Médecine de Paris held on Jan. 28th M. Guisez reported 21 cases in which foreign bodies had been extracted from the bronchi and œsophagus by broncho-œsophagoscopy during the year 1910. Among the objects removed from the bronchi were a fully opened penknife swallowed by a child aged 4 years, and a portion of a bone of a rabbit swallowed by a child aged 11 months. They were removed through the natural passages.

Feb. 6th.

## VIENNA.

(FROM OUR OWN CORRESPONDENT.)

*The Treatment of Progressive Paralysis of the Insane by Injections of Tuberculin.*

MUCH interest has been aroused lately by a preliminary report on the results obtained in one of our lunatic asylums by the injection of tuberculin in cases of progressive paralysis of the insane, and at a recent meeting of the Gesellschaft der Aerzte Dr. Pilcz, the director of the great asylum "Am Steinhof," read a paper on this subject. He said that the observations have been going on in the asylums here since Wagner in 1899 noticed that temporary remissions occurred in the condition of lunatics after an intercurrent febrile disease, such as erysipelas or septicæmia. Dr. Pilcz has had an opportunity of making investigations on two groups of paralytics, each numbering 100 cases and taken as they came, without any selection as regards the age of the patient or the duration of the mental symptoms. The treatment consisted in injecting Professor Koch's "old tuberculin" until a definite febrile reaction was obtained, and this was persisted in for several months. The result was that out of the group treated in that manner a smaller number died, and a larger number of cases were still alive and in a satisfactory condition after five years than out of the other group. Some of the patients were even able to resume their occupation. Dr. Pilcz subsequently selected 96 cases of recent progressive paralysis of the insane, and to each of these patients there was given a dose of at least 1-1000th of a milligramme of tuberculin in glycerine and sterilised water, the solution consisting of 1 part of Koch's old tuberculin, 4 parts of glycerine, and 5 parts of distilled water. The amounts of tuberculin were increased until, according to the reaction, doses rising from 2 centigrammes up to 50 centigrammes (from one-third of a grain up to 8 grains) were reached. This treatment was combined with antisyphilitic medication and small doses of thyroid substance. Out of 86 cases, whose history could be traced for years, the following results were known: 34 patients were not at all influenced, only short intermissions having occurred; in 20 cases the progress of the disease was arrested, but no objective improvement was observable; 9 patients were enabled to return to society, but not to earn their living; 23 patients of the total number resumed their occupation, and, with regard to their bodily and mental condition, they must be considered as having practically recovered. In no case did the inequality of the pupils disappear, but a large number of patients became well enough to make observations on the course of their disease. Dr. Pilcz said that there was very little, if any, danger of the injections producing acute tuberculosis; the post-mortem examinations never showed such a condition, and, as a rule, tuberculosis was hardly ever responsible for the death of this class of patients. If the physical examination showed a suspicious condition of the lungs the injections ought to be made with the utmost care. He did not wish to claim that the favourable results would be permanent, although some patients had remained in good health for over four years. At any rate, whether the recoveries were permanent or not, a mitigation of the disease for even a year or so must be regarded as sufficient to justify the treatment.

*Cysticercus of the Brain.*

At one of the last meetings of the Medical Society of

Vienna some cases and specimens were shown which illustrated the necessity of keeping in mind the possibility of the presence of a cysticercus in examining patients affected with cerebral disease. One of the cases was a man, aged 35 years, suffering from vertigo and nausea, with symptoms of old disease of the middle ear on both sides. The presence of vertical nystagmus confirmed the diagnosis of a centrally situated pathological condition. A diagnosis of cerebellar abscess was made, when suddenly all the symptoms disappeared, but returned after some time only to disappear again soon. A radical mastoid operation was, nevertheless, performed with exploratory investigation in the posterior cerebral fossa. No pus was found, but the man died suddenly. At the post-mortem examination a cysticercus of the fourth ventricle was found, which had caused an enormous fluid distension by occluding the foramen of Majendie. In another case the symptoms pointed to a tumour of the pons. The blood showed no abnormality and lumbar puncture gave a negative result. During the operation the patient died, and the post-mortem examination revealed a large cysticercus which had pressed upon the pontine region, causing various symptoms of tumour of the pons, such as deafness, tinnitus, papillœdema, and headache with dizziness. Of recent years such cases have been found occasionally in the otological clinics, for the aural symptoms predominated, or at least the symptoms were considered to originate in the ear, and in this way the patients were brought under the care of otologists before a physician saw them.

*Voluntary Production of Remarkable Bodily Abnormalities.*

A most unusual instance of the production of bodily abnormalities by means of auto-suggestion was shown by Dr. Hertz at a recent meeting of the Gesellschaft der Aerzte, the patient being a man who possessed such an extraordinary control over his physical organisation that he was even capable of voluntarily changing the position and size of his heart. He could reduce the frequency of its beats from 80 to 50 per minute, and he could bring it either into the right half of the thorax or into the middle line by suggesting to himself (1) that he was going too fast, or (2) that his left lung was collapsed. He could produce at will hyperæmia and swelling of any small area of the skin by auto-suggestion merely by impressing on his mind the belief that he had burnt himself at that spot. In addition to simultaneously dilating one of his pupils and contracting the other, he was able to produce contraction of several of his voluntary muscles one at a time, including the biceps, the triceps, the platysma myoides, the rectus abdominis, and the obliquus externus. He could also induce cutis anserina by voluntary excitation of the erectores pilorum muscles. His appearance was truly remarkable when he made a simultaneous display of his various accomplishments.

Feb. 6th.

## NEW YORK.

**(FROM OUR OWN CORRESPONDENT.)**

*Opium Smuggling.*

A SENSATION has been caused by a Federal police raid on six Chinese shops in cheap neighbourhoods of New York, conducted ostensibly for the sale of tea and Oriental curios only, and the seizure therein of an immense quantity of opium, prepared for smoking, which had been smuggled. Letters were found implicating the police officials of several large Western cities by demonstrating friendly relations with a notorious Chinaman long suspected of smuggling, not only opium, but Chinese themselves. Opium prepared for smoking looks very much like the common solid extract, but it is only about half the strength of the latter. It is sold in lychee nuts, replacing the kernel, which has been deftly removed. It is said that there are over 100,000 white smokers of opium in the United States, but these are all recruited from the criminal class, petty gamblers, and the like. Indulgence in the habit consumes from four to seven hours daily, and is, therefore, not likely to become the vice of persons employed in any legitimate occupation. The importance of the raid lies in the letters seized along with the opium, several of which, it is said, refer to the murderer of Elsie Sigel, a young white girl teacher in Chinese Sunday schools, whose body was found concealed in a trunk in the Chinese quarter some months ago. The singular attraction which the Chinese exert on religiously minded young women of a certain type is worthy the attention of psychiatrists.

*The Child's Welfare Exhibition.*

An exhibition of what is being done for the children of New York opened in one of the large National Guard armouries on Jan. 18th, and will remain open till Feb. 12th. Admission is free except on two days of the week, when a charge of 1*s.* is made, and visitors from all classes of society may be found there in thousands at all times. Charts, photographs, and models of various kinds line the walls, while an open space in the centre is given up to folk dancing, school drills, and gymnastic exhibitions by public school children. Moving pictures show similar performances in foreign lands. Perhaps the most popular section is that showing typical homes of the New York poor. A three-room flat is shown furnished at an expense of £20. On one side of this there is a model nursery and playroom for a large family of children. Another playroom for two children is furnished entirely with articles home-made from packing-cases, the expense being supposed to be *nil* save for paint, screws, &c. Clothing suitable for an entire family living on an income of £160 is one of the exhibits. Toys have been made a subject of scientific study, and a toyshop filled with toys approved by experts shows the ethical and educational value of properly selected playthings. Two boys are at work showing how serviceable toys may be made at home with a fret saw and pocket-knife. Hundreds of pictures show children playing in the streets and demonstrate the dangers of impure candy, cheap shows, dance halls, and heavy traffic. The work of the Board of Education is fully illustrated, from the duties of the visiting physician and nurse to the cooking-schools, shop work, and kindergartens. Actual children's libraries are shown and a librarian advises as to what books a child should read. The department of laws and administration has collected data as to the workings of all the children's courts in the country, most of them superior to the children's court of New York. The committee on work and wages emphasises painfully the heavy penalty the child pays in body and soul in return for the low money wage given for his work. What is being done for the care of needy children at home and abroad is illustrated. Modern scientific care of defective children is represented, especially the work among feeble-minded, epileptic, deaf, dumb, and blind. There is a model orphan asylum on the cottage plan as the best substitute for the home. As people in all these models are represented by artistically and suitably dressed dolls, the attention of children is easily involved and they become eager to make more than one visit to the exhibition, and to bring their little friends and their parents. Other departments illustrate the work of social settlements in their efforts to furnish social centres in the congested districts. and to supplant dangerous gangs and back-room clubs, while in one corner the work of the churches, temples, and Sunday schools of all denominations is demonstrated. In a small theatre under the armoury frequent popular lectures are given by well-known authorities. A completely equipped dental establishment shows the hope of dentists to establish compulsory dental examination of all school children with possible free treatment. A laboratory shows how to pasteurise milk.

*Two Recent City Ordinances.*

The Board of Aldermen has passed a law forbidding the wearing by women of hatpins the points of which project more than one inch beyond the brim of the hat, unless the points are protected by some rounded metal device. There have been many serious wounds of the cheek and eye in the crowded trains of the subway and elevated road.——The sale of raw milk is now forbidden within the city, and all dealers must equip their bottling plants with the requisite apparatus for pasteurisation. There are three grades of milk allowed: "infant's feeding," which may be sold at a considerable premium; "drinking milk," which must be of known origin, but not necessarily of the highest percentage of fats; and "cooking milk," which will be all that of dubious pedigree, or from dairies concerning which the health authorities have doubts.

*Non-Poisonous Matches.*

One of the largest match manufacturing corporations has

voluntarily abandoned the use of phosphorus and has declined to patent the process for the use of the "sesquisulphide process," which will allow its use by all other match companies. This action was due to the direct influence of the President. Great interest has been excited in Canada by this fact, and a Bill has been introduced into the Dominion Parliament forbidding the manufacture or importation of phosphorus matches. The Bill is being bitterly opposed by Canadian manufacturers.

*The Case of Margaret Shipley.*

At Mackeesport, Penn., a young girl, blind from birth, went into an apparent trance under the influence of religious excitement on Jan. 24th. She promised to awake on the 31st with her vision restored. The awaking occurred but not the hoped-for miracle. Visitors to the afflicted child have been numbered literally by the scores of thousands, many of them loud-voiced believers, and the spectacle around the patient's house has recalled the stories of similar sights in the Middle Ages. The child's parents were apparent believers and had made arrangements in order to found a brand-new religion on Jan. 31st. Despite the disappointment of the devout, there is strong belief among many of a mere postponement of the manifestation of some supernatural power.

*Conflict between Federal and State Law.*

The law in the State of New York against the sale of cocaine is very severe and pretty generally observed. A physician who was treating a patient for the cocaine habit found that the latter was getting his supplies from New Hampshire, and appealed to the Federal authorities to arrest the shippers. A reply from the Government official stated his regret that no law prevented the sending of cocaine through the mails, which are under exclusive Federal control. The State of New York thus finds itself powerless to enforce its own prohibition against the sale of cocaine, since the sale is made outside its boundaries. No State can pass any law affecting the post office.

Jan. 31st.

# Obituary.

## CALEB BARRETT, F.R.C.S. ENG., L.S.A. LOND.

Mr. Caleb Barrett died recently at his residence, Henry-street, Bath, at the age of 90 years.

He received his medical education at King's College Hospital, London, and qualified as L.S.A. Lond. in 1844. In 1858 he passed the examination for the F.R.C.S. Eng. Mr. Barrett, in the early part of his career, was in practice at Gloucester, where he was surgeon to the infirmary and also to the Children's Hospital. He afterwards went to Bath, where he practised for many years. He was medical officer to the Southern Dispensary in that city, and for a considerable time medical officer to the Abbey and Weston districts of the Bath Union, but he resigned these appointments in 1899, and shortly afterwards retired from active work. His wife predeceased him a few years ago. Mr. Barrett was highly respected in Bath, and by his death that city loses one of her oldest and most esteemed medical practitioners.

## JUSTIN THEODORE VULLIAMY, M.R.C.S. ENG., L.R.C.P. LOND.

IT is with much regret that we record the unexpected death of Mr. Justin Theodore Vulliamy, which took place at his residence in Rugby on Jan. 23rd, in his forty-second year.

Mr. Vulliamy was the eldest son of Mr. Theodore Vulliamy of Ware, and was born at Nonancourt, in the department of the Eure in Normandy, France, and passed his early boyhood in the pleasant scenery which characterises that district. He there acquired the thorough knowledge of French which proved so useful to him in after life. His education was continued at Uppingham School and afterwards at St. Thomas's Hospital Medical School, where he was a dresser in the surgical wards to Mr. Bernard Pitts. He did not take any special part in the sessional examinations, but devoted himself to acquiring a good general knowledge of his profession from the practical side, and gained the esteem of those with whom he was associated for his steady devotion to duty of every kind. In 1897 he obtained the qualifications of the Conjoint Board in London, and became M.R.C.S. Eng. and L.R.C.P. Lond.

For a time he acted as one of the resident medical officers to the Royal Free Hospital. He then became house physician to the Hospital for Consumption and Diseases of the Chest, Brompton; house surgeon to the French Hospital; and assistant house surgeon to the Lincoln County Hospital. Some ten years ago he joined Messrs. Simpson and Relton in their practice at Rugby, and soon made himself known as an enthusiast in his desire to advance the general knowledge of the public in all matters concerning hygiene and public health. He gave lectures on nursing, hygiene, and ambulance duty for the Midland Counties Educational Union, and became surgeon to the Rugby Provident Dispensary. A few months ago he was appointed an assistant surgeon to the Rugby Hospital, and was perhaps happier in this appointment than in any other, for his previous training had well fitted him for dealing with the more important surgical and operative work which came to him. He was essentially a man devoted to his profession, and never refused to obey the call of duty, however great the personal inconvenience of so doing. "Duty" always came first—indeed, it is very probable that this intense and somewhat over-anxious devotion to his work undermined his health and rendered him less able to withstand the attack of influenzal pneumonia which so quickly proved fatal. The large and representative attendance at the memorial service in Rugby proved the esteem in which he was held by all who knew him. Three years ago he married Dora, daughter of Mr. Dunbar Kilburn of Gloucester-square, London.

## FREDERICK WILLIAM PEARCE JAGO, M.B. LOND., M.R.C.S., L.S.A.

Mr. F. W. P. Jago died at his residence, Lynher House, St. Germans, Cornwall, on Feb. 1st, at the advanced age of 93 years. The deceased, who belonged to an old Cornish family, received his medical education at the London Hospital. He graduated as M.B. Lond. in 1848, and in the same year obtained the M.R.C.S. Eng. and L.S.A. qualifications. He shortly afterwards went to Plymouth, where he practised his profession for 50 years. He was highly esteemed in the "Three Towns," and at one time had an extensive practice. He contributed several articles to the medical journals. He took a great interest in all matters connected with Cornwall, and was the author of "The Ancient Language and the Dialect of Cornwall," and the compiler of an "English-Cornish Dictionary." About 12 years ago Mr. Jago left Plymouth and took up his residence at St. Germans. The deceased was a staunch member of the Church of England, and up to the end took a great interest in all Church matters. He leaves a daughter, who has been for a long time his devoted and faithful companion.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Juan R. Fernandez, a distinguished member of the Medical Faculty of the Buenos Aires University, at the age of 50. He was born in Corrientes and studied medicine in Buenos Aires and in Paris. In 1890 he was appointed professor of midwifery and afterwards dean of the Faculty of Buenos Aires. During the presidency of General Roca he was Minister of Public Education, and to him many important improvements are due, including the school for midwives, of which he himself acted as director for a time, the Morgue, the National Institute of Secondary Teachers, the Normal School of Living Languages, and the Palace of Justice.—Dr. von Gussmann of Stuttgart, director of the Medical and Sanitary Department of the Würtemberg Government, aged 70.—Dr. Degen, chief medical officer of the Fürth Municipal Hospital, whose name is well known in connexion with the Social Democrat Party. He was 70 years of age.

The Hon. W. F. D. Smith, chairman of the King's College Hospital Removal Fund, has most generously promised to pay the cost of building one of the central ward blocks of the new hospital, which, it is estimated, will cost £30,000.

# Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Düsseldorf (Academy of Practical Medicine):* Dr. Christian Bruhn has been recognised as *privat-docent* of Odontology.—*Kiel:* Dr. Adam Bauereisen, who followed his chief, Professor Stoeckel, from Marburg, has been recognised as *privat-docent* in Gynæcology.—*Naples:* Dr. Michelangelo Cipolla has been recognised as *privat-docent* of Dermatology.—*Palermo:* Dr. Gaetano Lodato has been promoted to the chair of Ophthalmology.—*Philadelphia (University of Pennsylvania):* Dr. Milton B. Hartzell has been appointed to the chair of Dermatology, in succession to Dr. Louis A. Duhring, resigned.—*Prague (German University):* As successor to Dr. Gad, the professor of physiology, who is about to retire, the name of Dr. F. B. Hoffmann, professor in Innsbruck, is mentioned.—*Rome:* Dr. Francesco Pulvizenti has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Sassari:* Dr. Andrea Pietri has been recognised as *privat-docent* of Surgery.—*Tübingen:* Dr. C. Brodmann has been recognised as *privat-docent* of Neurology and Psychiatry.

DONATIONS AND BEQUESTS.—Mr. Harold Nickols has given £10,000 to the Lord Mayor of Leeds' Fund for the General Infirmary in memory of King Edward VII.—Among the latest contributions received at the Bank of England for King Edward's Hospital Fund for London are the following annual subscriptions: Mr. Walter Morrison, £5000; Mr. William Waldorf Astor, £1000.—The late Rev. Montague Earle Welby left by will £2500 to the Middlesex Hospital and £2500 to the Lock Hospital and Rescue Home.

ESPERANTO AND MEDICINE.—At the Hampden Club Debating Society on Feb. 6th Mr. Kenneth W. Millican, B.A. Cantab., M.R.C.S. Eng., gave an address on Esperanto, in which he pointed out the great need for a common language at medical congresses and the loss to medical progress which resulted from the failure to establish a common means of intercommunication. Important discoveries were sometimes made by medical men abroad and recorded in a language not understood by the medical world as a whole. Much valuable information might thus be lost and only rediscovered after lapse of time.

THE SECOND INTERNATIONAL CONGRESS OF UROLOGY.—This congress will be held in London from July 24th to 28th, 1911. At the meeting of the First International Congress, held in Paris on Oct. 1st, 1908, Mr. E. Hurry Fenwick was chosen as the president of the Second International Congress, and Professor A. Koranyi of Budapest and Professor A. Pousson of Bordeaux were elected vice-presidents. The questions to be discussed at the forthcoming congress are: (1) Phosphaturia and Oxaluria, reported by M. Hogge (Liège), M. Péchère (Brussels), M. Richter (Berlin), and M. Teissier (Lyons); (2) Late Results of Prostatectomy, by Dr. Hugh Young (Baltimore, U.S.A.), Señor Regino Gonzales (Mexico), and Professor Zuckerkandl (Vienna); (3) Extensive Removals of the Bladder Wall, by Mr. Hurry Fenwick (London), Signore Giordano (Venice), and Herre Rovsing (Copenhagen). Mr. John Pardoe, 77, Wimpole-street, London, W., is the secretary of the congress.

VAGRANTS AND THE WAY-TICKET SYSTEM.—The county of Sussex has for some years played an important part in dealing with vagrants, and by means of its way- and food-ticket system has been rewarded with considerable success in reducing the number of vagrants relieved at the various unions. The system provides assistance for the genuine workman in search of employment and tends to decrease the number of professional beggars and habitual vagrants. Any scheme that succeeds in driving the professional tramp class off the roads is deserving of success, but it is only by coöperating between boards of guardians that this end can be secured. The professional tramp, for whom not a good word can be said, and the habitual vagrant, who more often than not tramps the country dragging with him his wife and many children, will then quickly find out the districts where the treatment meted out to them is very different to that which greets the genuine workman in search of work, and in those districts the professionals will become few and far between. The ne'er-do-wells will be driven to the taskwork imposed by the casual laws from which the genuine workman "on the road" will be exempted as he is under the way-ticket system.

Lord Charles Beresford will preside at the annual dinner of the London School of Clinical Medicine to be held at Princes Restaurant on Friday, March 24th.

THE Amiens School of Medicine and Pharmacy has been closed owing to the frequent disorders which have recently occurred there. It is stated that during a lecture a student fired ten revolver shots in the hall, the bullets going through the ceiling.

PRESENTATION TO A MEDICAL MAN.—On Feb. 2nd Dr. Andrew Elliot, who has just retired from the office of honorary medical registrar at the West London Hospital, was presented, on the occasion of his marriage, with a silver tray by some past and present members of the hospital staff.

LITERARY INTELLIGENCE.—Messrs. W. B. Saunders Company announce the publication of "The Collected Papers by Drs. W. J. and C. H. Mayo and their Associates at St. Mary's Hospital, Rochester, U.S.A." The papers are illustrated with original drawings showing the pathology and histology of the conditions considered and the technique employed in treatment.
